

# Algorithms 2012: Dynamic Programming

(Based on [Cormen *et al.* 2009])

Yih-Kuen Tsay

## 1 Design Methods

### Design Methods

- Greedy
- Divide-and-Conquer
- **Dynamic Programming**
- Branch-and-Bound
- ...

## 2 Dynamic Programming

### Principles of Dynamic Programming

- Property of Optimal Substructure (Principle of Optimality):  
*An optimal solution to a problem contains optimal solutions to its subproblems.*
- A particular subproblem or subsubproblem typically recurs while one tries different decompositions of the original problem.
- To reduce running time, optimal solutions to subproblems are computed only once and stored (in an array) for subsequent uses.

### Development by Dynamic Programming

1. Characterize the structure of an optimal solution.
2. Recursively define the value of an optimal solution.
3. Compute the value of an optimal solution in a bottom-up fashion.
4. Construct an optimal solution from computed information.

### 3 Matrix-Chain Multiplication

#### Matrix-Chain Multiplication

**Problem 1.** Given a chain  $A_1, A_2, \dots, A_n$  of matrices where  $A_i$ ,  $1 \leq i \leq n$ , has dimension  $p_{i-1} \times p_i$ , fully parenthesize (i.e., find a way to evaluate) the product  $A_1 A_2 \dots A_n$  such that the number of scalar multiplications is minimum.

- Why is dynamic programming a feasible approach?
- To evaluate  $A_1 A_2 \dots A_n$ , one first has to evaluate  $A_1 A_2 \dots A_k$  and  $A_{k+1} A_{k+2} \dots A_n$  for some  $k$  and then multiply the two resulting matrices.
- An optimal way for evaluating  $A_1 A_2 \dots A_n$  must contain optimal ways for evaluating  $A_1 A_2 \dots A_k$  and  $A_{k+1} A_{k+2} \dots A_n$  for some  $k$ .

#### Matrix-Chain Multiplication (cont.)

Let  $m[i, j]$  be the minimum number of scalar multiplications needed to compute  $A_i A_{i+1} \dots A_j$ , where  $1 \leq i \leq j \leq n$ .

$$m[i, j] = \begin{cases} 0 & \text{if } i = j \\ \min_{i \leq k < j} \{m[i, k] + m[k + 1, j] + p_{i-1} p_k p_j\} & \text{if } i < j \end{cases}$$

#### Matrix-Chain Multiplication (cont.)

**Algorithm Matrix\_Chain\_Order**( $n, p$ );

**begin**

**for**  $i := 1$  to  $n$  **do**

$m[i, i] := 0$ ;

**for**  $l := 2$  to  $n$  **do** {  $l$  is the chain length }

**for**  $i := 1$  to  $(n - l + 1)$  **do**

$j := i + l - 1$ ;

$m[i, j] := \infty$ ;

**for**  $k := i$  to  $(j - 1)$  **do**

**if**  $m[i, k] + m[k + 1, j] + p[i - 1]p[k]p[j] < m[i, j]$  **then**

$m[i, j] := m[i, k] + m[k + 1, j] + p[i - 1]p[k]p[j]$

**end**

#### Recursive Implementation

**Algorithm Recursive\_Matrix\_Chain**( $p, i, j$ );

**begin**

**if**  $i = j$  **then return** 0;

$m[i, j] := \infty$ ;

**for**  $k := i$  to  $(j - 1)$  **do**

$q := \text{Recursive\_Matrix\_Chain}(p, i, k) +$

$\text{Recursive\_Matrix\_Chain}(p, k + 1, j) + p[i - 1]p[k]p[j]$ ;

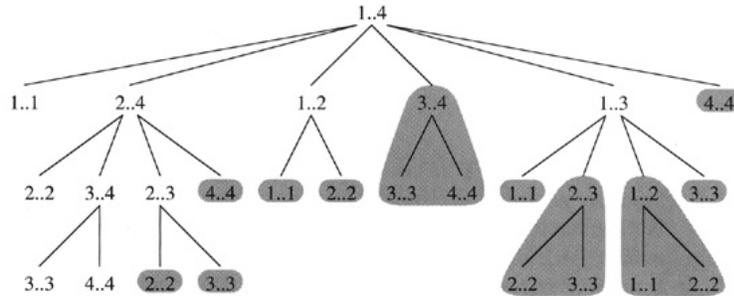

**if**  $q < m[i, j]$  **then**

$m[i, j] := q$ ;

**return**  $m[i, j]$

**end**

## Recursive Implementation (cont.)

**Figure 15.5** The recursion tree for the computation of `RECURSIVE-MATRIX-CHAIN(p, 1, 4)`. Each node contains the parameters  $i$  and  $j$ . The computations performed in a shaded subtree are replaced by a single table lookup in `MEMOIZED-MATRIX-CHAIN(p, 1, 4)`.

Source: [Cormen *et al.* 2006].

## Recursion with Memoization

```

Algorithm Memoized_Matrix_Chain( $n, p$ );
begin
  for  $i := 1$  to  $n$  do
    for  $j := i$  to  $n$  do
       $m[i, j] := \infty$ ;
    return Lookup_Matrix_Chain( $p, i, n$ )
end

```

## Recursion with Memoization (cont.)

```

Procedure Lookup_Matrix_Chain( $p, i, j$ );
begin
  if  $m[i, j] < \infty$  then return  $m[i, j]$ ;
  if  $i = j$  then
     $m[i, j] := 0$ ;
  else
    for  $k := i$  to  $(j - 1)$  do
       $q :=$  Lookup_Matrix_Chain( $p, i, k$ ) +
        Lookup_Matrix_Chain( $p, k + 1, j$ ) +  $p[i - 1]p[k]p[j]$ ;
      if  $q < m[i, j]$  then
         $m[i, j] := q$ ;
    return  $m[i, j]$ 
end

```

## 4 Single-Source Shortest Paths

### Single-Source Shortest Paths

**Problem 2.** Given a weighted directed graph  $G = (V, E)$  with no negative-weight cycles and a vertex  $v$ , find (the lengths of) the shortest paths from  $v$  to all other vertices.

- Notice that edges with negative weights are permitted; so, Dijkstra's algorithm does not work here.
- A shortest path from  $v$  to any other vertex  $u$  contains at most  $n - 1$  edges.
- A shortest path from  $v$  to  $u$  with at most  $k$  ( $> 1$ ) edges must be composed of a shortest path from  $v$  to  $u'$  with at most  $k - 1$  edges and the edge from  $u'$  to  $u$ , for some  $u'$ .

### Single-Source Shortest Paths (cont.)

Denote by  $D^l(u)$  the length of a shortest path from  $v$  to  $u$  containing *at most*  $l$  edges; particularly,  $D^{n-1}(u)$  is the length of a shortest path from  $v$  to  $u$  (with no restrictions).

$$D^1(u) = \begin{cases} \text{length}(v, u) & \text{if } (v, u) \in E \\ 0 & \text{if } u = v \\ \infty & \text{otherwise} \end{cases}$$

$$D^l(u) = \min\{D^{l-1}(u), \min_{(u', u) \in E} \{D^{l-1}(u') + \text{length}(u', u)\}\}, \\ 2 \leq l \leq n - 1$$

### Single-Source Shortest Paths (cont.)

**Algorithm Single\_Source\_Shortest\_Paths**( $\text{length}$ );

**begin**

$D[v] := 0;$

**for all**  $u \neq v$  **do**

**if**  $(v, u) \in E$  **then**

$D[u] := \text{length}(v, u)$

**else**  $D[u] := \infty;$

**for**  $k := 2$  **to**  $n - 1$  **do**

**for all**  $u \neq v$  **do**

**for all**  $u'$  such  $(u', u) \in E$  **do**

**if**  $D[u'] + \text{length}[u', u] < D[u]$  **then**

$D[u] := D[u'] + \text{length}[u', u]$

**end**

## 5 All-Pairs Shortest Paths

### All-Pairs Shortest Paths

**Problem 3.** *Given a weighted directed graph  $G = (V, E)$  with no negative-weight cycles, find (the lengths of) the shortest paths between all pairs of vertices.*

- Consider a shortest path from  $v_i$  to  $v_j$  and an arbitrary intermediate vertex  $v_k$  (if any) on this path.
- The subpath from  $v_i$  to  $v_k$  must also be a shortest path from  $v_i$  to  $v_k$ ; analogously for the subpath from  $v_k$  to  $v_j$ .

### All-Pairs Shortest Paths (cont.)

Index the vertices from 1 through  $n$ .

Denote by  $W^k(i, j)$  the length of a shortest path from  $v_i$  to  $v_j$  going through no vertex of index greater than  $k$ , where  $1 \leq i, j \leq n$  and  $0 \leq k \leq n$ ; particularly,  $W^n(i, j)$  is the length of a shortest path from  $v_i$  to  $v_j$ .

$$W^0(i, j) = \begin{cases} \text{length}(i, j) & \text{if } (i, j) \in E \\ 0 & \text{if } i = j \\ \infty & \text{otherwise} \end{cases}$$

$$W^k(i, j) = \min\{W^{k-1}(i, j), W^{k-1}(i, k) + W^{k-1}(k, j)\}, 1 \leq k \leq n$$

### All-Pairs Shortest Paths (cont.)

**Algorithm All\_Pairs\_Shortest\_Paths(*length*);**

**begin**

**for**  $i := 1$  to  $n$  **do**

**for**  $j := 1$  to  $n$  **do**

**if**  $(i, j) \in E$  **then**  $W[i, j] := \text{length}(i, j)$

**else**  $W[i, j] := \infty$ ;

**for**  $i := 1$  to  $n$  **do**  $W[i, i] := 0$ ;

**for**  $k := 1$  to  $n$  **do**

**for**  $i := 1$  to  $n$  **do**

**for**  $j := 1$  to  $n$  **do**

**if**  $W[i, k] + W[k, j] < W[i, j]$  **then**

$W[i, j] := W[i, k] + W[k, j]$

**end**
