

# Confidentiality Using Symmetric Encryption

Tsay, Yih-Kuen

Dept. of Information Management  
National Taiwan University

# Confidentiality

- 🌐 Providing **confidentiality** through the use of **secret-key encryption** has historically been the focus of cryptology.
- 🌐 This topic remains important in itself, though other considerations have emerged in the last few decades.
- 🌐 An understanding of the issues involved here
  - ☀️ clarifies those in other applications of encryption and
  - ☀️ helps to **motivate** the development of **public-key encryption**.

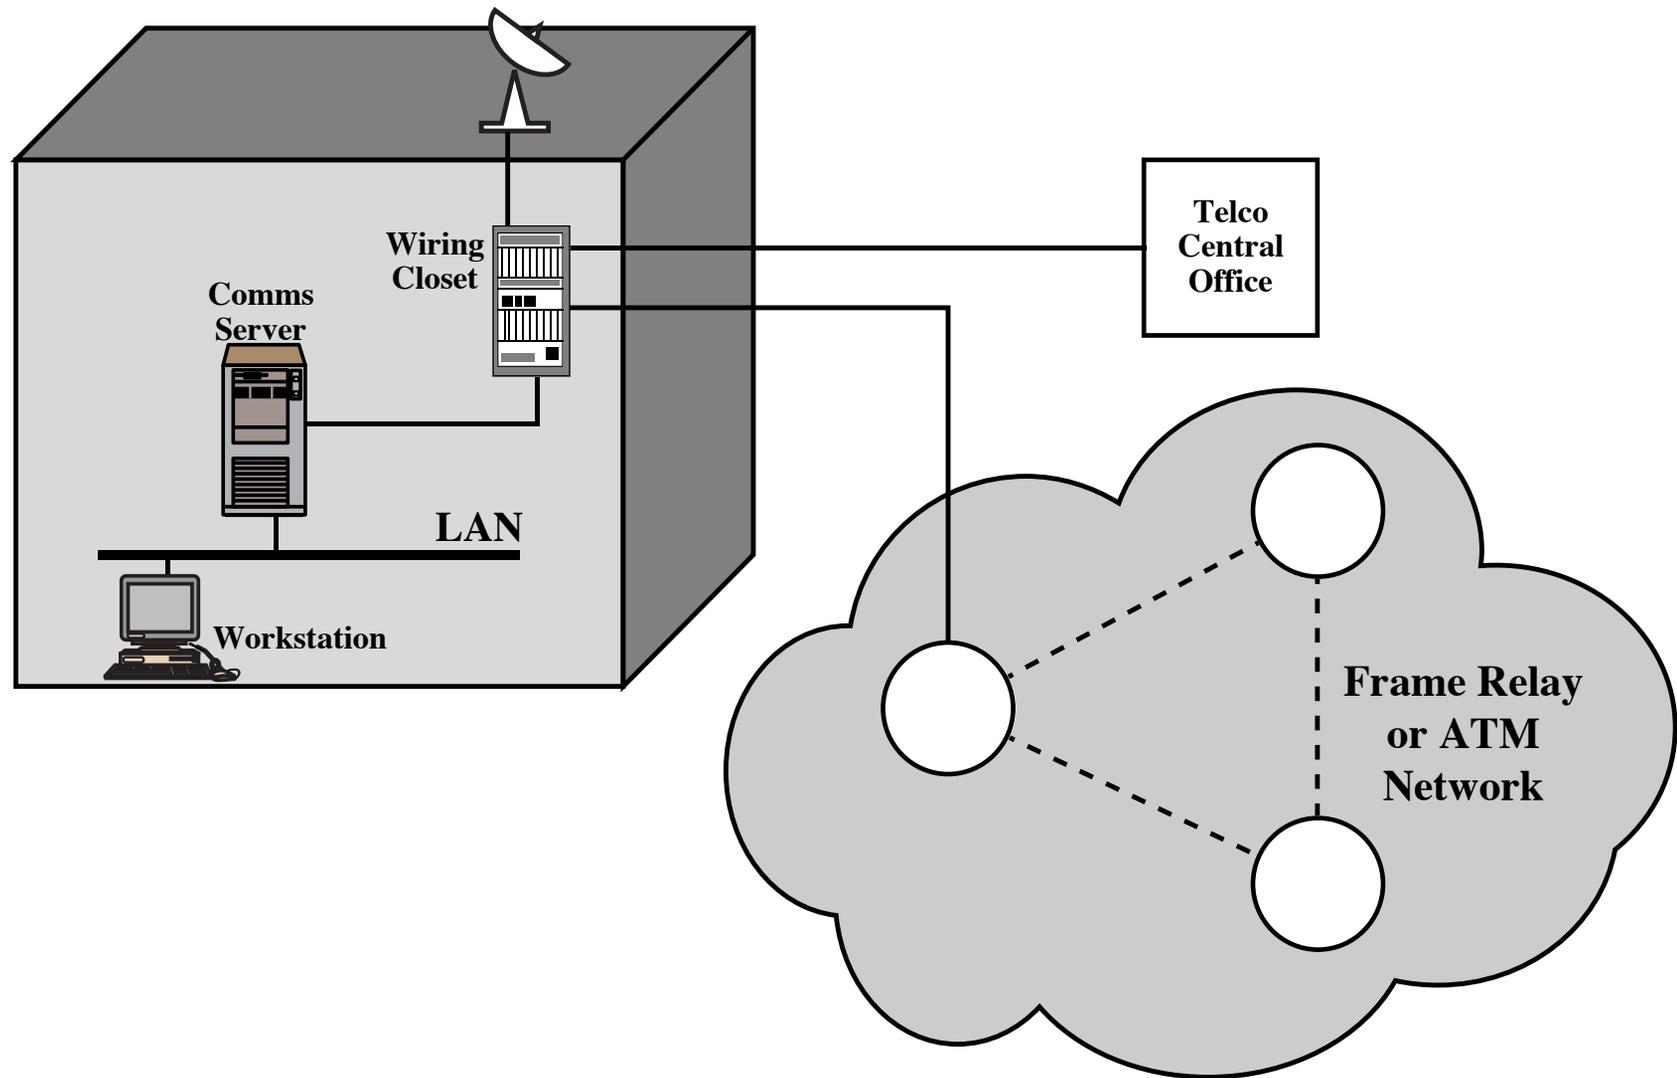

# Placement of Encryption Function

- 🌐 Issues involved:
  - ☀️ **What** should be encrypted?
  - ☀️ **Where** should encryption be done?
- 🌐 Two approaches:
  - ☀️ **Link** encryption
  - ☀️ **End-to-end** encryption
- 🌐 To make the decisions, one should first examine the potential locations of security attacks.

# Points of Vulnerability

Source: Figure 7.1, Stallings 2006

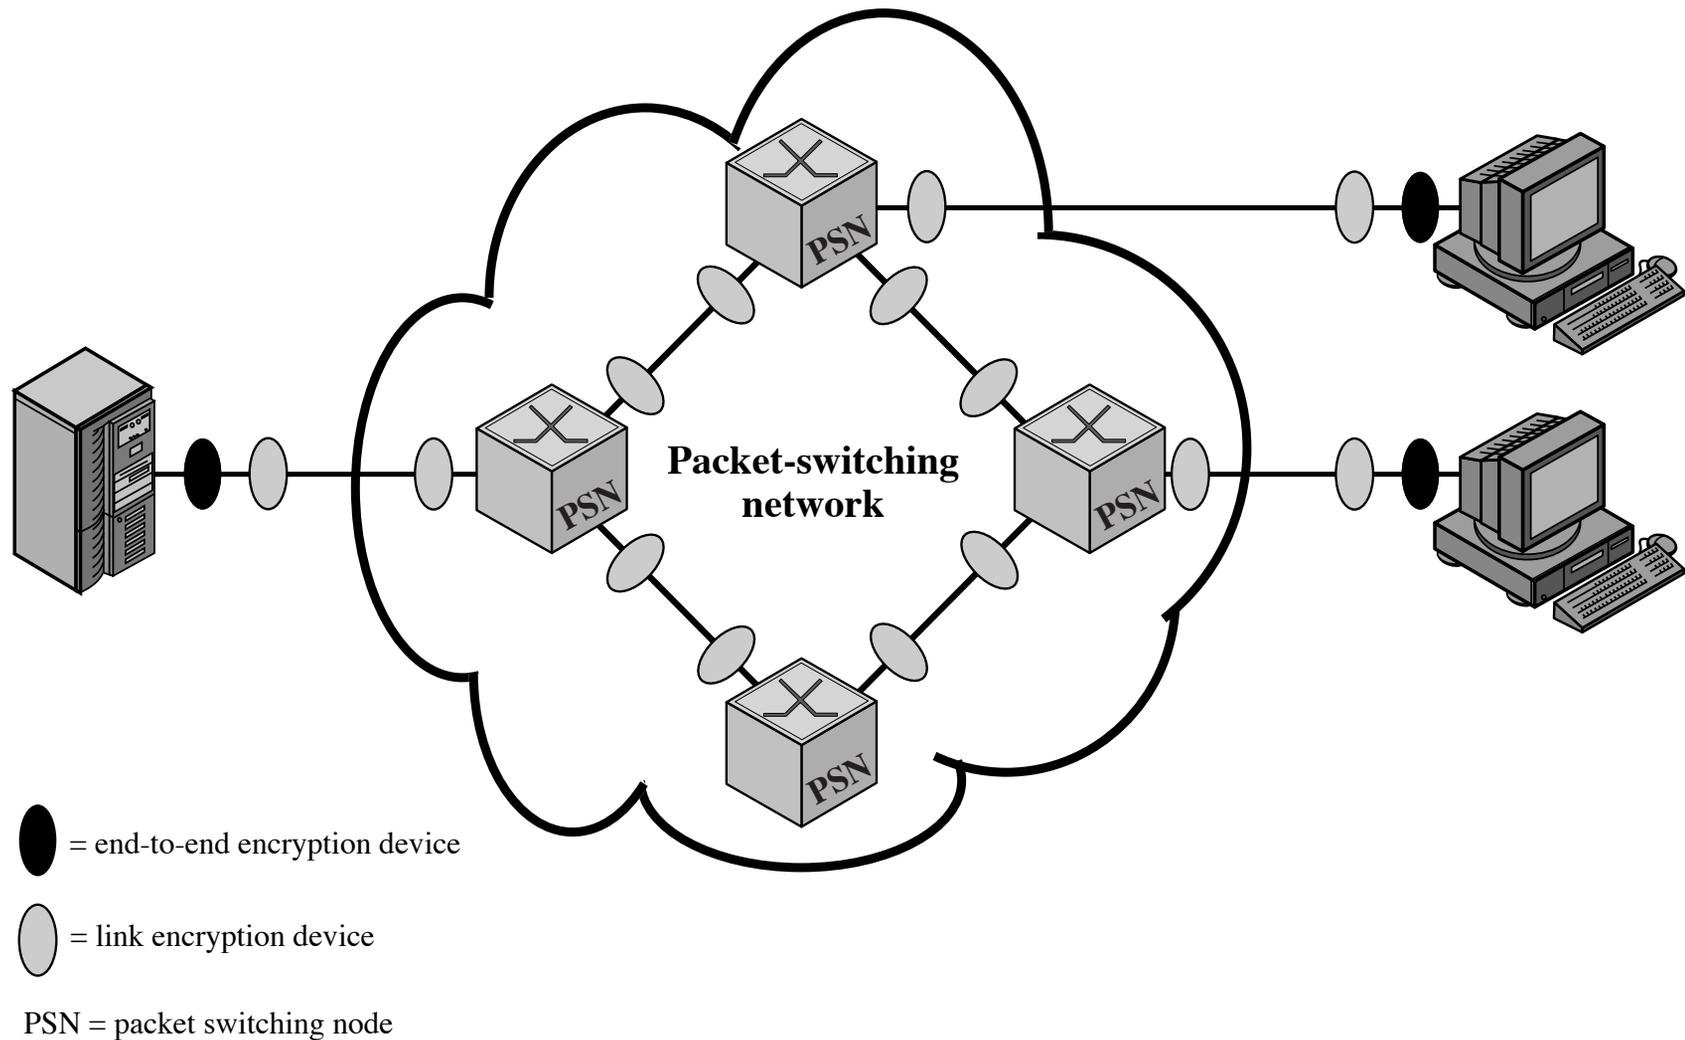

# Locations for Confidentiality Attacks

Consider a user workstation in a typical business organization. The points of vulnerability include:

- 🌐 The **LAN** that the workstation is attached to: *eavesdropping* on the LAN, which is typically a *broadcast* network.
- 🌐 The **Wiring closet**: tapping the wires.
- 🌐 **Communications links** out of the Wiring closet: invasive or inductive tapping.
- 🌐 **Processors** along the path to the outside: modifying the hardware or software, etc.

# Encryption in Packet-Switching Networks

Source: Figure 7.2, Stallings 2006

# Link Encryption

- 🌐 **Each** vulnerable communications **link** is equipped on both ends with an encryption device. Thus, all traffic over all communications links is secured.
- 🌐 The message must be decrypted each time it enters a packet switch. Thus, the message is **vulnerable at each switch**.
- 🌐 **Many keys** must be provided. However, each key needs be distributed to only two nodes.

# End-to-End Encryption

- 🌐 The encryption process is carried out **at the two end systems**. The source and the destination share a key.
- 🌐 This plan seems to secure the transmission against attacks on the network links or switches. There is, however, still a weak spot.
- 🌐 The source may **encrypt only the user data portion**, but must leave **the header in the clear**.
- 🌐 With end-to-end encryption, the user data are secure, but the **traffic pattern** is not. A certain degree of authentication is also provided.

# Link vs. End-to-End Encryptions

<b>Link Encryption</b>	<b>End-to-End Encryption</b>
<i>Security within End Systems and Intermediate Systems</i>	
Message exposed in sending host Message exposed in intermediate nodes	Message encrypted in sending host Message encrypted in intermediate nodes
<i>Role of User</i>	
Applied by sending host Transparent to user Host maintains encryption facility One facility for all users Can be done in hardware All or no messages encrypted	Applied by sending process User applies encryption User must determine algorithm Users selects encryption scheme Software implementation User chooses to encrypt, or not, for each message
<i>Implementation Concerns</i>	
Requires one key per (host-intermediate node) pair and (intermediate node-intermediate node) pair Provides host authentication	Requires one key per user pair Provides user authentication

Source: Table 7.1, Stallings 2006

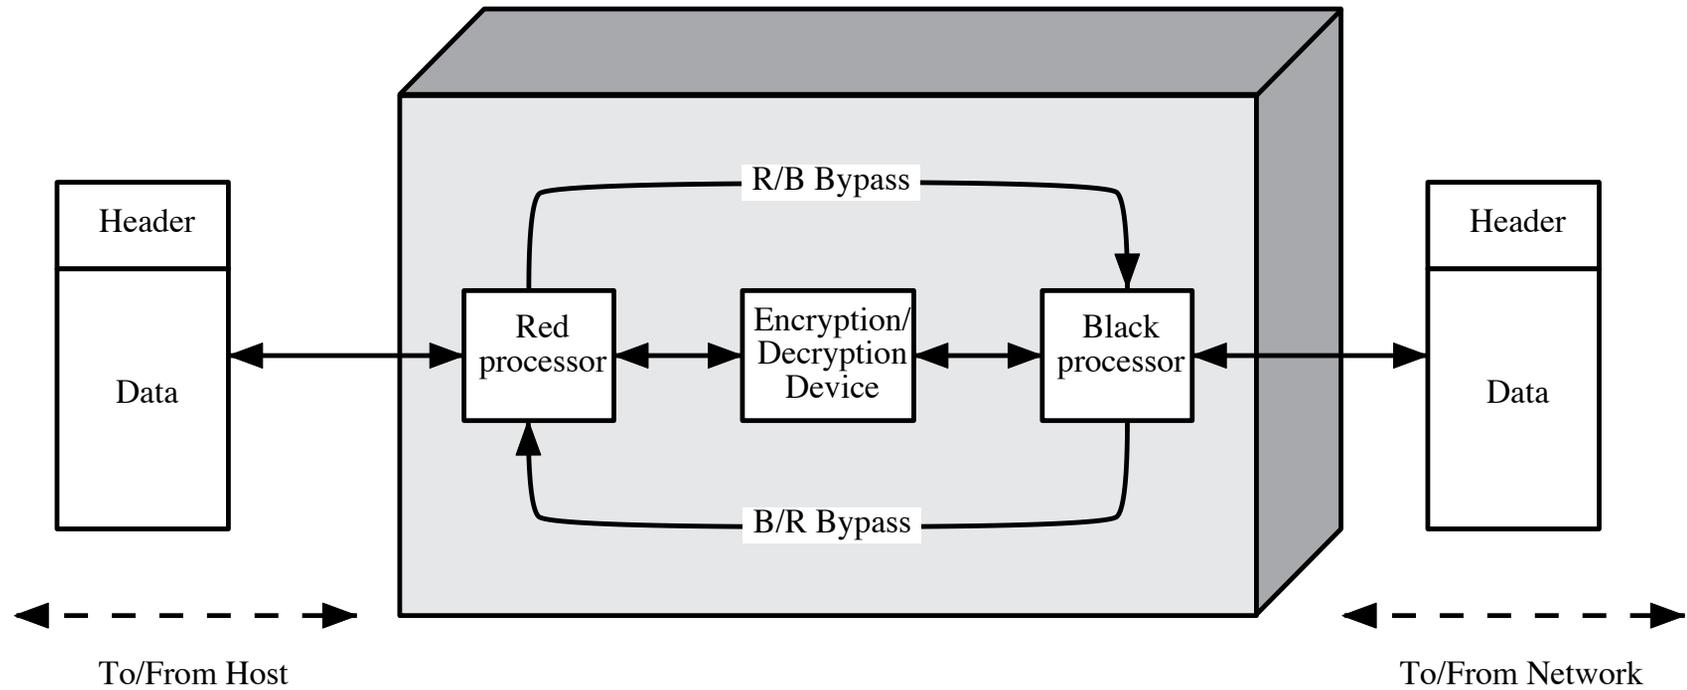

# Deploying End-to-End Encryption

Possible choices:

- 🌐 The **network** layer or the **transport** layer
  - ☀️ one key for each pair of end systems
  - ☀️ cannot cross internetwork boundaries
- 🌐 The **application** layer
  - ☀️ many keys needed: one key for each pair of users
  - ☀️ can cross internetwork boundaries

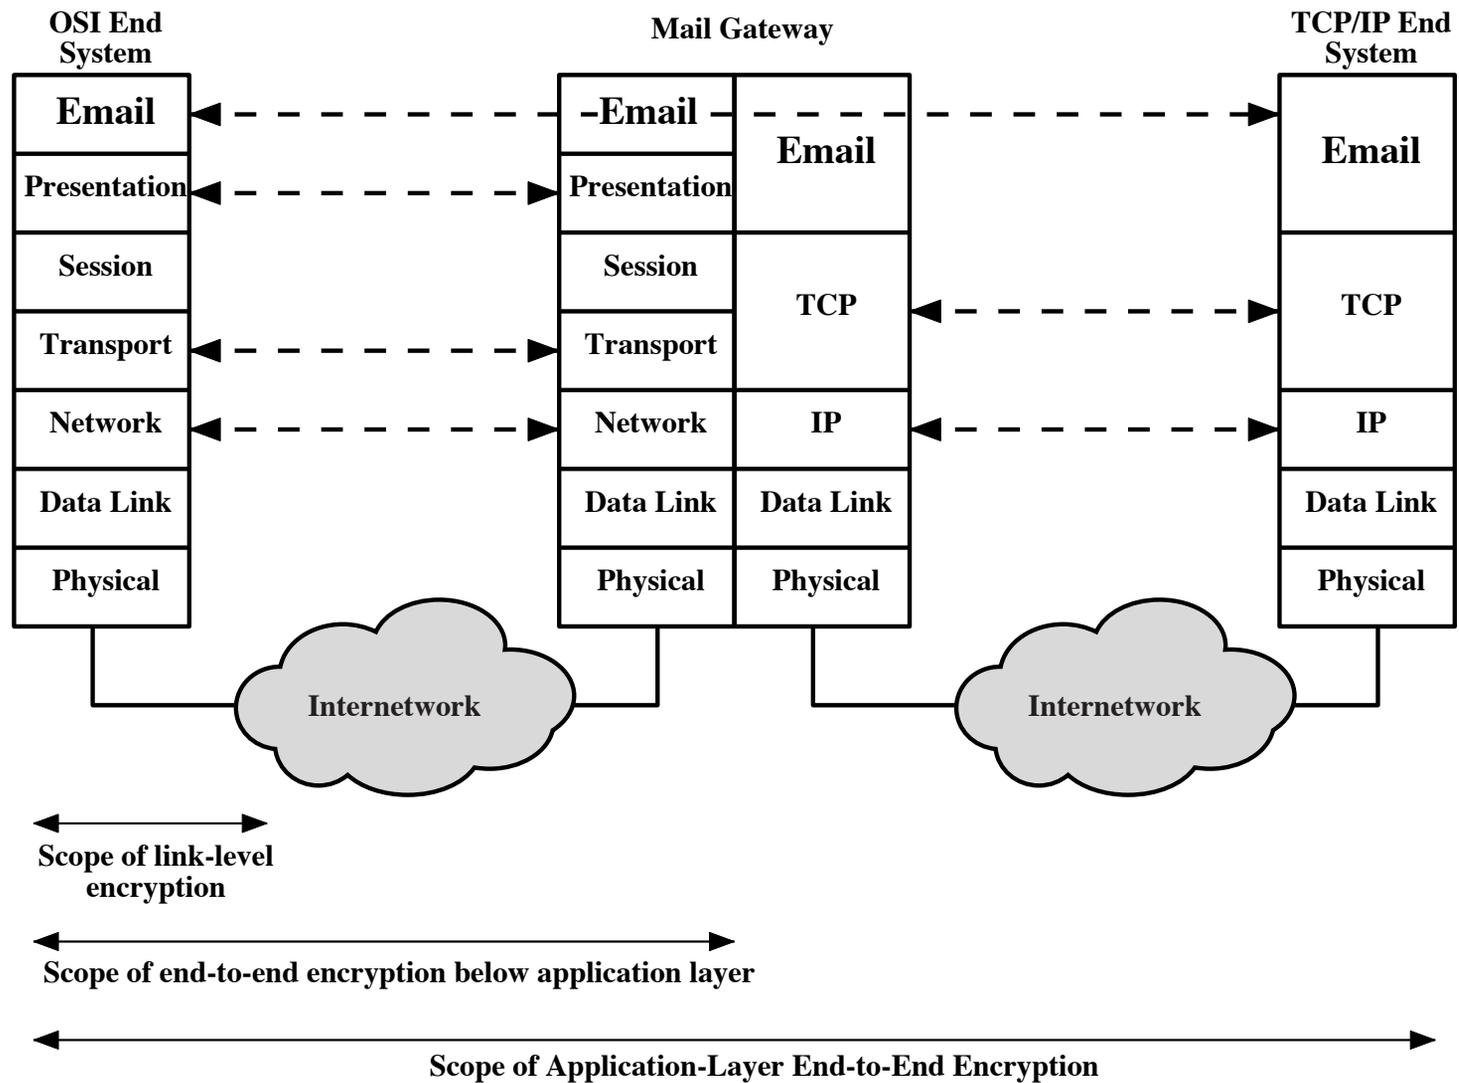

# Front-End Processor Function

# Encryption and Protocol Layers

(a) Application-Level Encryption (on links and at routers and gateways)

On links and at routers

In gateways

(b) TCP-Level Encryption

On links

In routers and gateways

(c) Link-Level Encryption

Shading indicates encryption.

- TCP-H = TCP header
- IP-H = IP header
- Net-H = Network-level header (e.g., X.25 packet header, LLC header)
- Link-H = Data link control protocol header
- Link-T = Data link control protocol trailer

Source: Figure 7.5, Stallings 2006

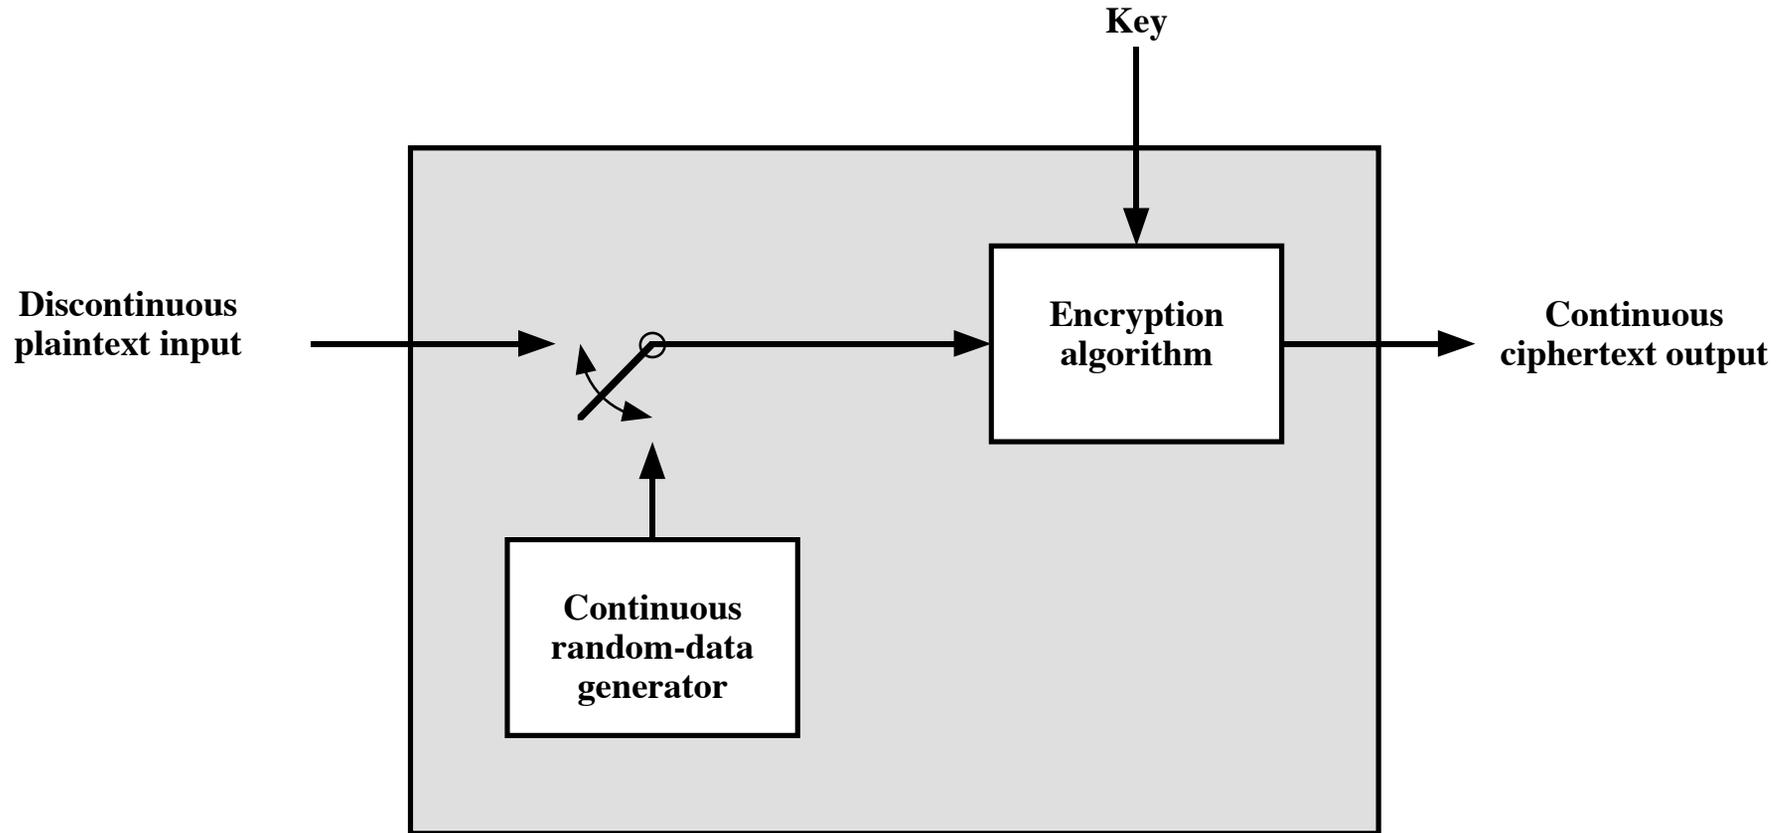

# Traffic Confidentiality

Types of information that can be **derived from a traffic analysis attack**:

- 🌐 Identities of partners
- 🌐 How frequently the partners are communicating
- 🌐 Message pattern, message length, or quantity of messages
- 🌐 Events correlated with conversations between particular partners
- 🌐 Messages of a *covert channel*

# Traffic Padding

Source: Figure 7.6, Stallings 2006

# Countering Traffic Analysis

- 🌐 Link encryption approach
  - ☀️ packet headers already encrypted
  - ☀️ further strength via traffic **padding**
- 🌐 End-to-end encryption approach: available measures more limited
  - ☀️ padding out data units to a uniform length
  - ☀️ inserting null messages randomly

# The Key Distribution Problem

- 🌐 For symmetric encryption to work, the two parties of an exchange **must share the same key** and **that key must be protected**.
- 🌐 **Frequent key changes** may be desirable to limit the amount of data compromised.
- 🌐 The strength of a cryptographic system rests with the technique for solving the **key distribution problem**—delivering a key to the two parties of an exchange.
- 🌐 The scale of the problem depends on the number of communication pairs.

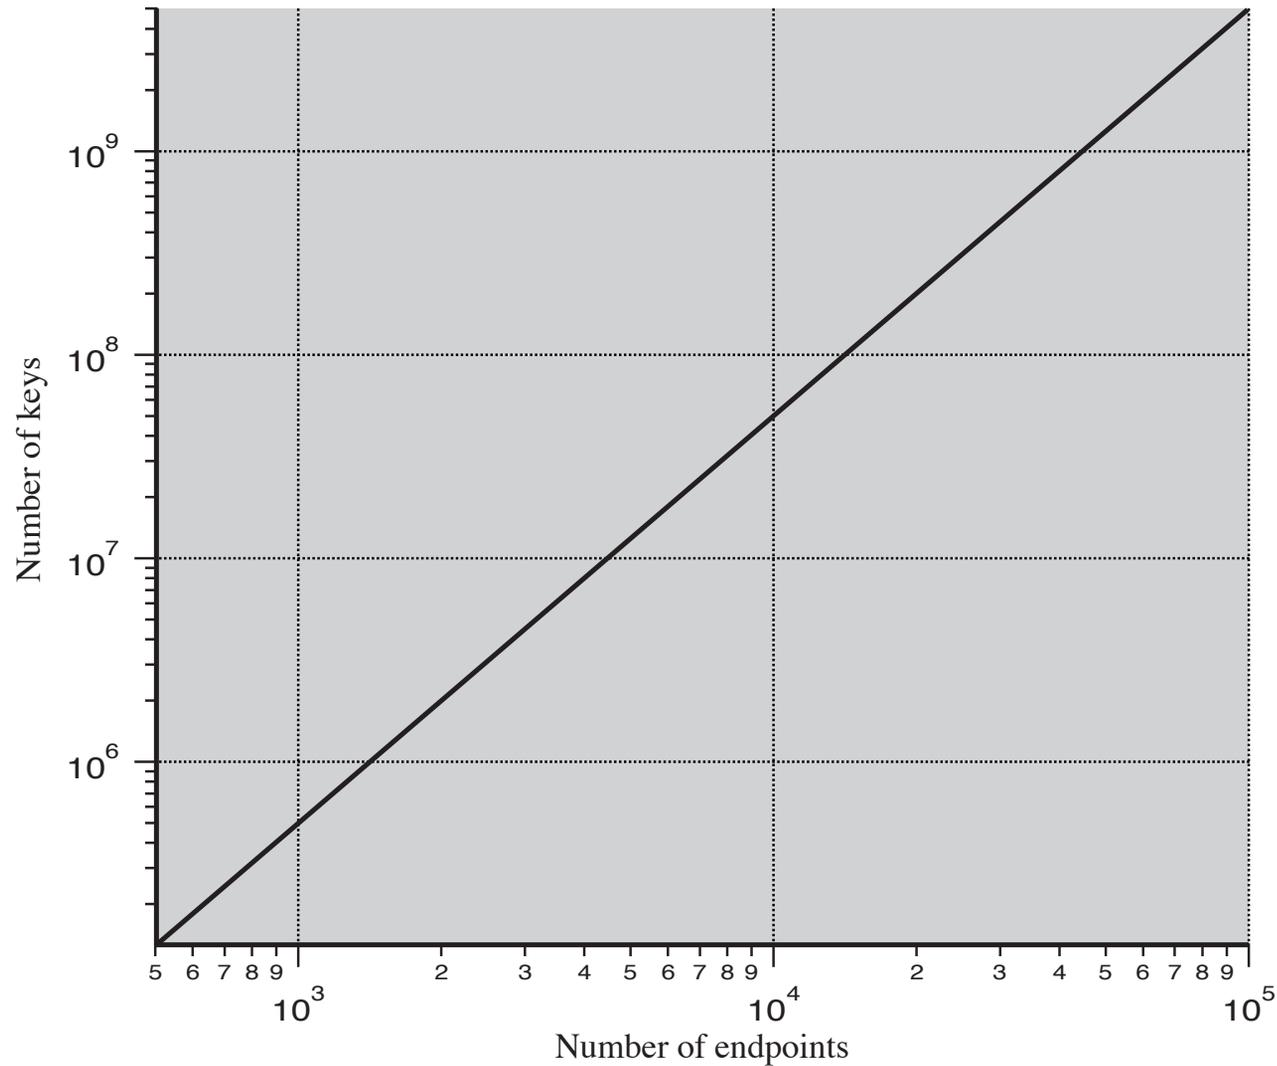

# Approaches to Key Distribution

Let A (Alice) and B (Bob) be the two parties.

- 🌐 A key can be selected by A and **physically** delivered to B.
- 🌐 A **third party** can select the key and **physically** deliver it to A and B.
- 🌐 If A and B **have previously and recently used a key**, one party can transmit the new key to the other, encrypted using the old key.
- 🌐 If A and B each **has an encrypted connection to a third party C**, C can deliver a key on the encrypted links to A and B.

# Number of Keys for Endpoints

Source: Figure 7.7, Stallings 2006

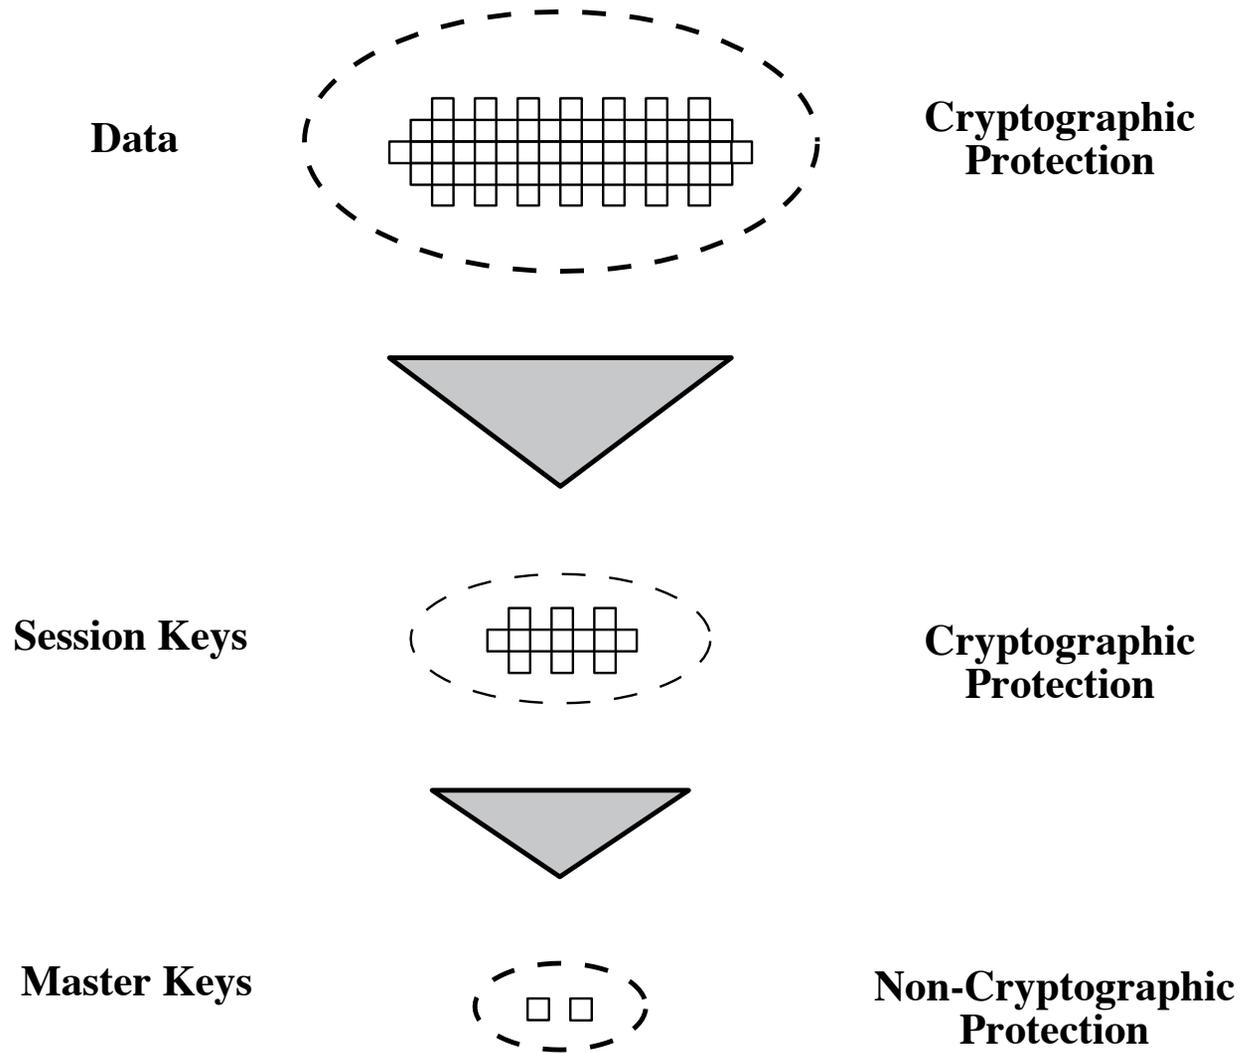

# Using a Key Distribution Center

- 🌐 A **key distribution center** is responsible for distributing keys to pairs of users as needed.
- 🌐 Each user must share a unique key with the key distribution center for purposes of key distribution.
- 🌐 At least two levels of keys must be used: **session keys** and **master keys**.
- 🌐 If there are  $N$  end users,  $N(N - 1)/2$  session keys are needed at any one time, but only  $N$  master keys are required.

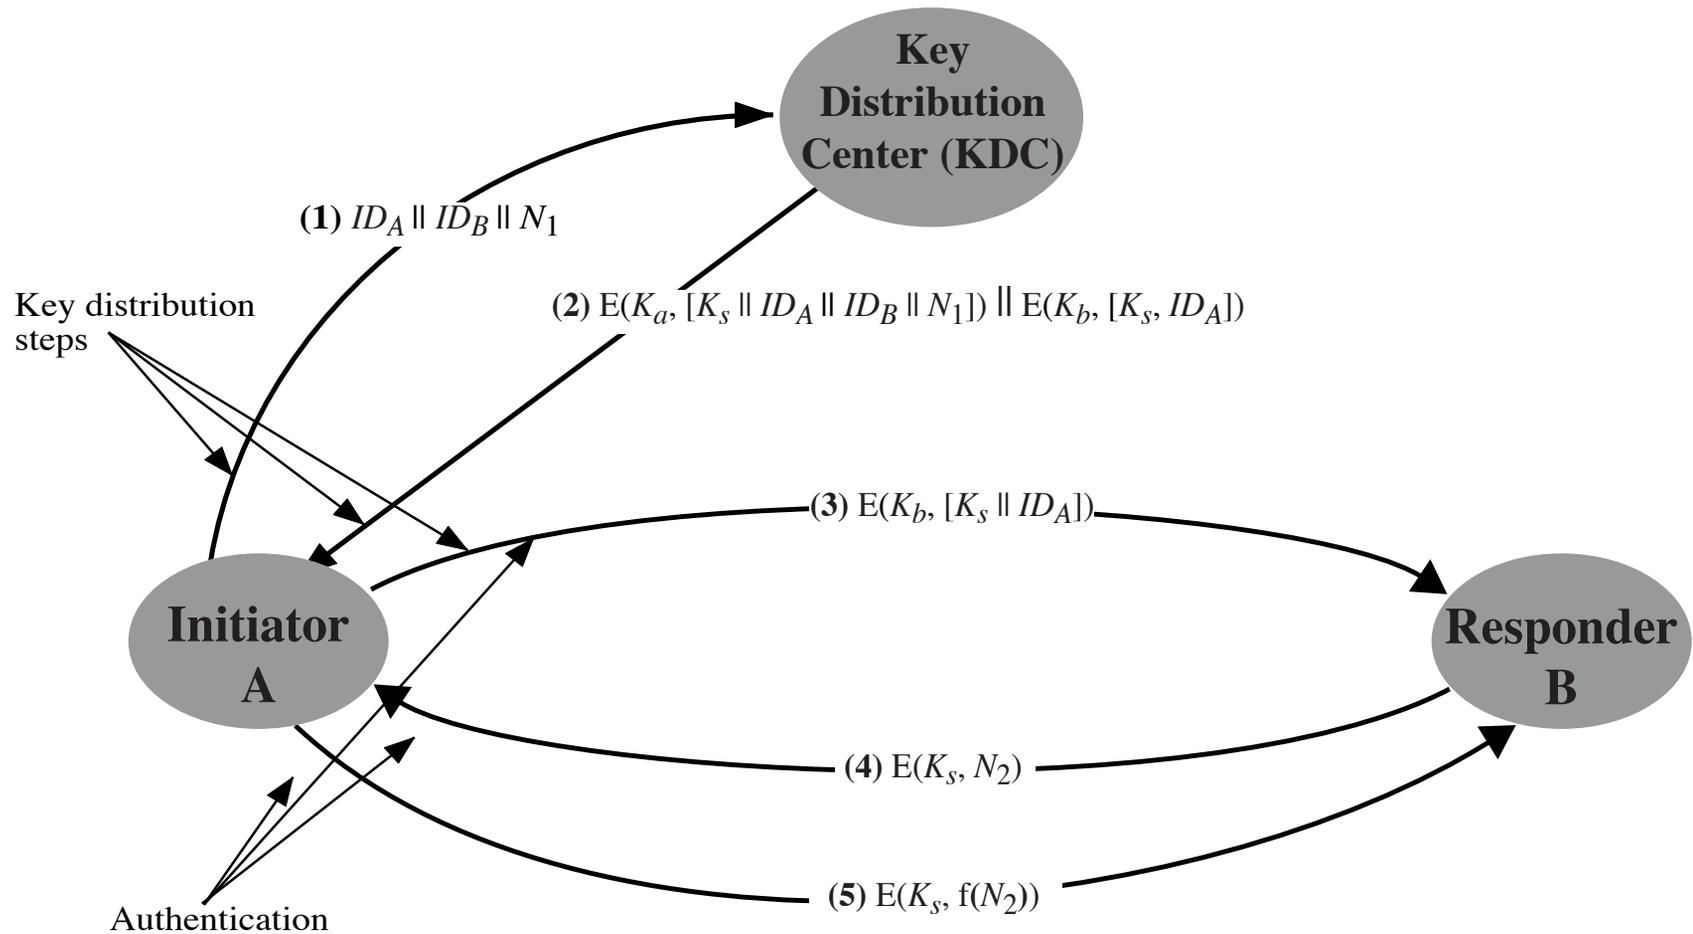

# Key Hierarchy

Source: Figure 7.8, Stallings 2006

# Key Distribution Scenario

Source: Figure 7.9, Stallings 2006

# Hierarchical Key Control

- 🌐 For large networks, a single KDC is inadequate.
- 🌐 In a hierarchy of KDCs, each local KDC is responsible for a small domain.
- 🌐 If the two parties are within the same local domain, their KDC is responsible for key distribution.
- 🌐 Otherwise, the two corresponding local KDCs can communicate through a global KDC. Any of the three KDCs involved can select the key.
- 🌐 Advantages: distributing the effort of master key distribution and **isolating the damage of a fault**.

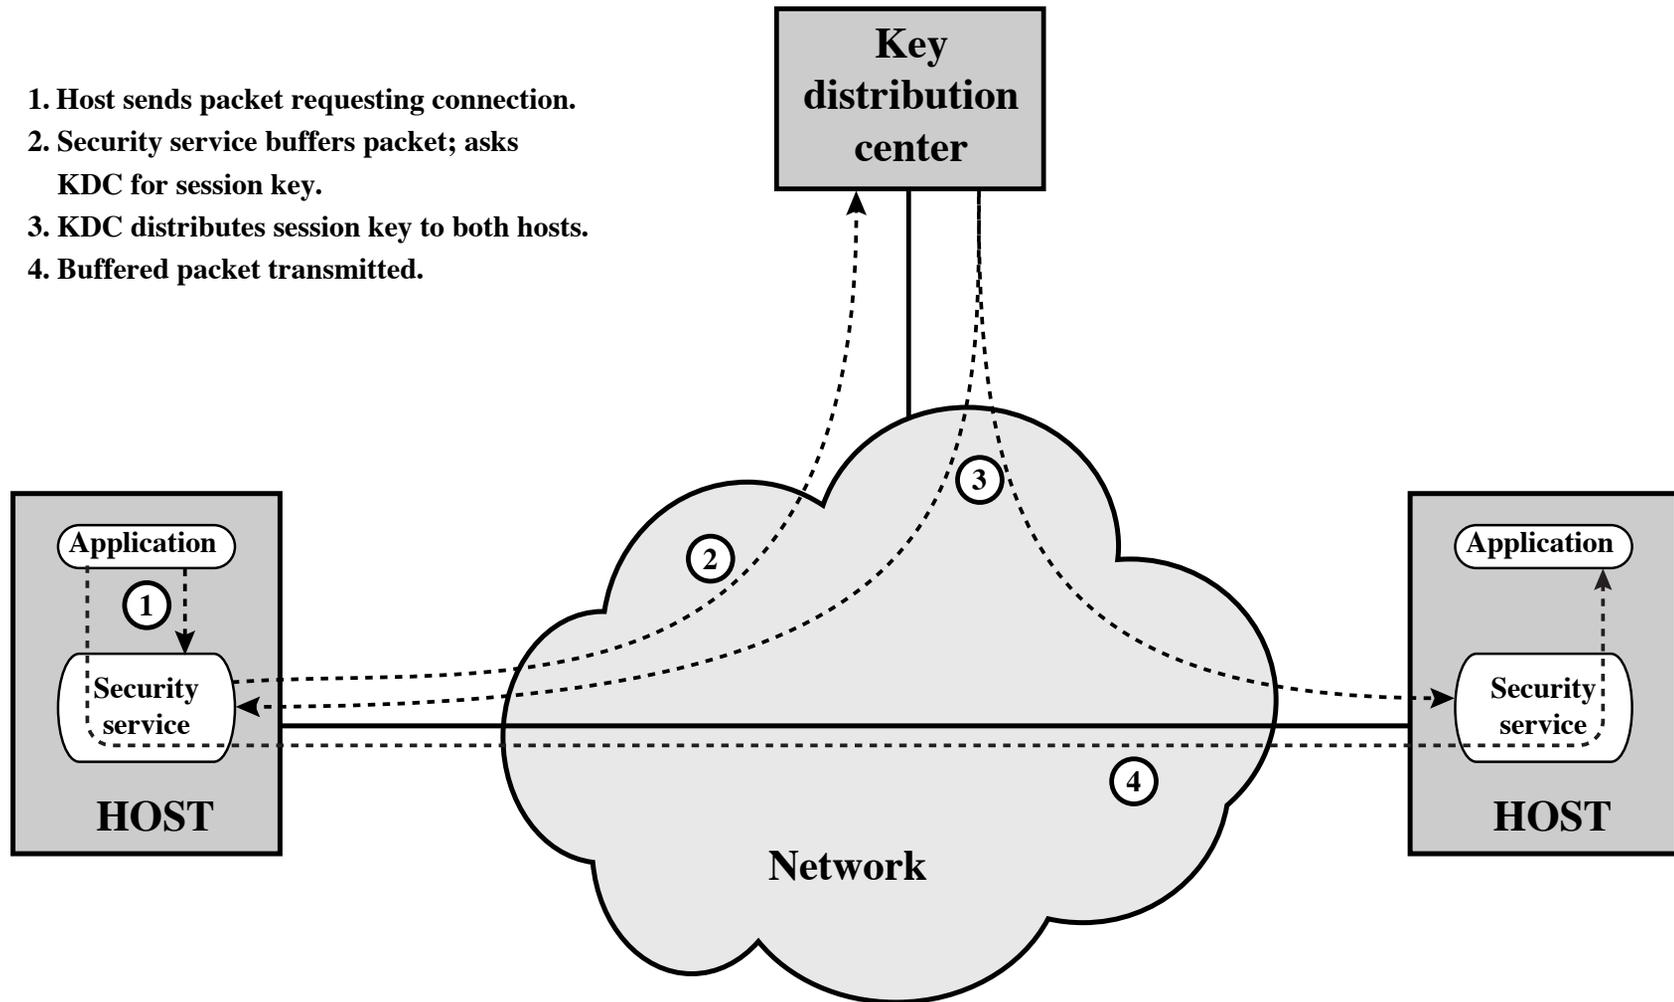

# Session Key Lifetime

- 🌐 Two competing considerations in determining the lifetime of a session key:
  - ☀️ The more frequently session keys are changed, the more secure they are.
  - ☀️ The distribution of session keys delays the start of an exchange and places a burden on network capacity.
- 🌐 The decision can be based on whether the communication protocol is connection-oriented or connectionless.

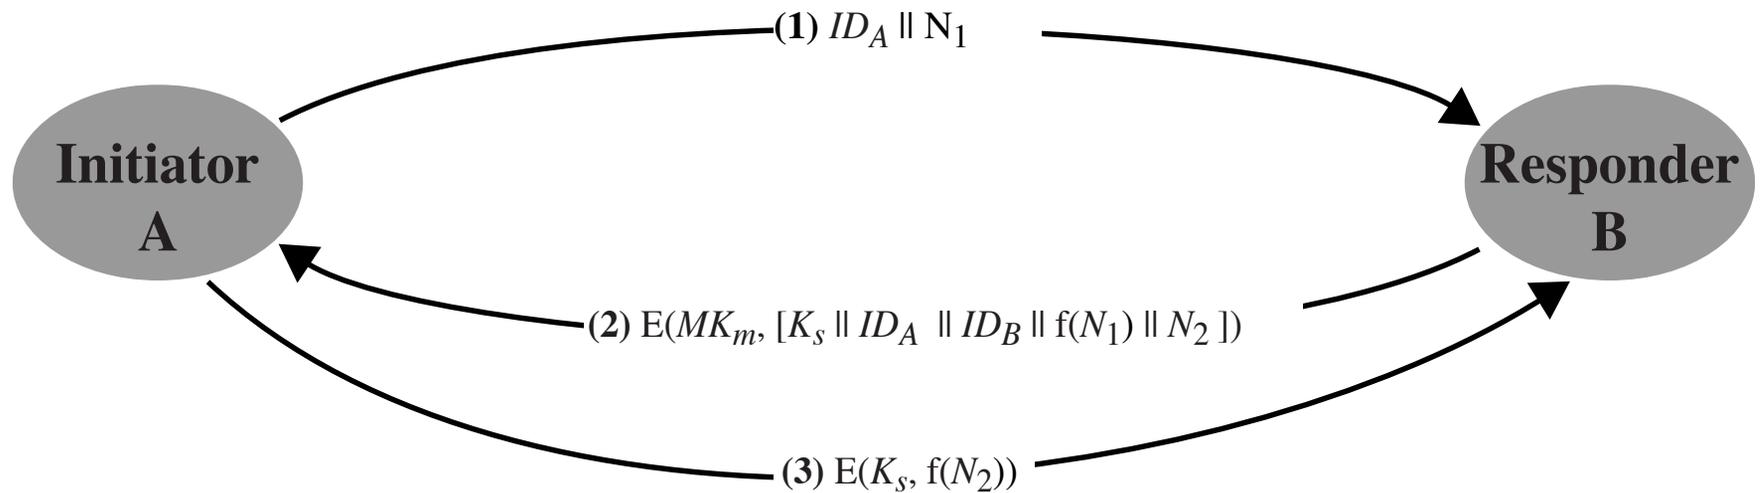

# Automatic Key Distribution

1. Host sends packet requesting connection.
2. Security service buffers packet; asks KDC for session key.
3. KDC distributes session key to both hosts.
4. Buffered packet transmitted.

Source: Figure 7.10, Stallings 2006

# Decentralized Key Distribution

Source: Figure 7.11, Stallings 2006

# Decentralized Key Control

- 🌐 The KDC must be trusted and be protected from subversion.
- 🌐 This requirement can be avoided if the key distribution is fully decentralized.
- 🌐 A fully decentralized key control, though not feasible for large networks, may be **useful within a local context**.
- 🌐 A decentralized approach requires that each end system be able to communicate in a secure manner with all potential partner end systems for purposes of session key distribution.

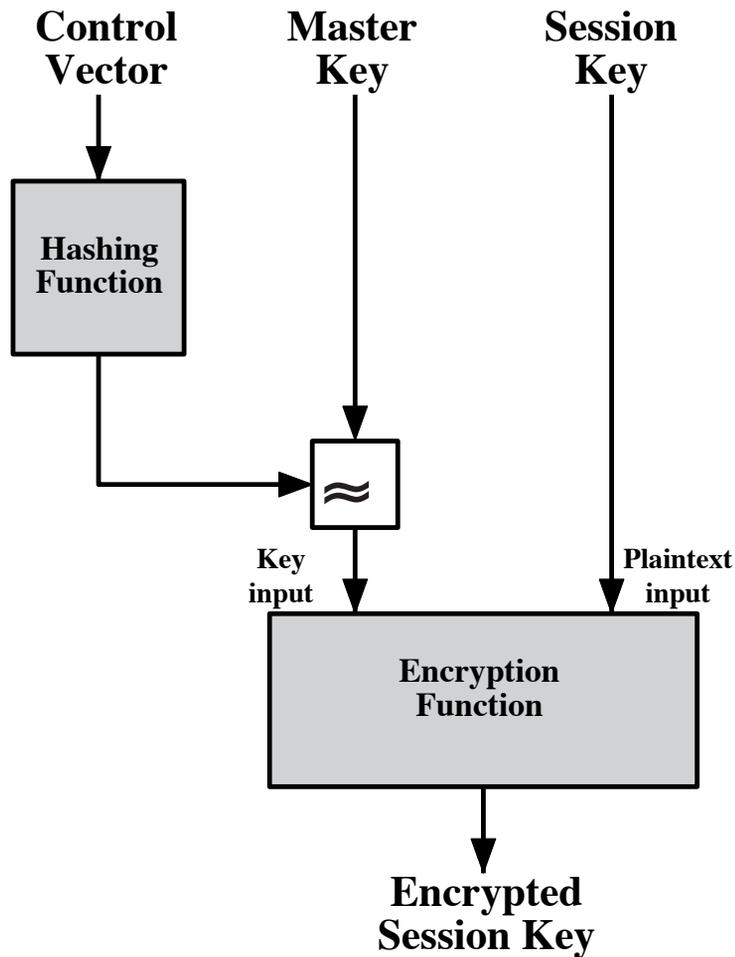

# Controlling Key Usage

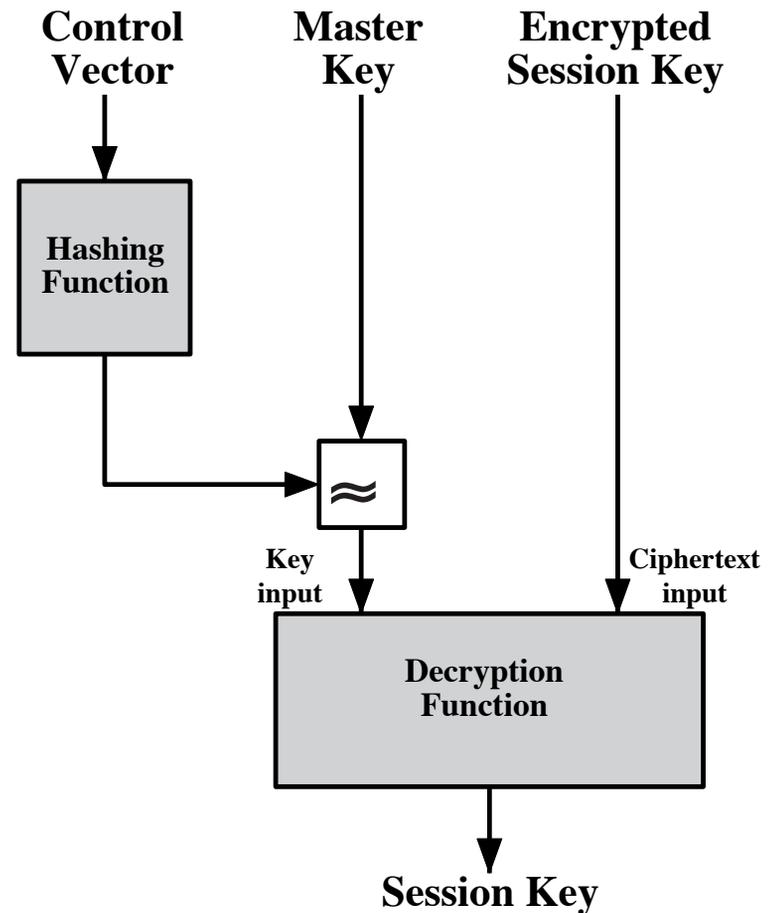

- 🌐 It may be desirable to impose some control on the way in which automatically distributed keys are used.
- 🌐 Possible types of session keys include: data-encrypting key, PIN-encrypting key, file-encrypting key, etc.
- 🌐 Key use controlling schemes:
  - ☀️ Tags
  - ☀️ Control vectors

# Control Vector

(a) Control Vector Encryption

(b) Control Vector Decryption

Source: Figure 7.12, Stallings 2006

# The Use of Random Numbers

- 🌐 Random numbers are used by a number of security algorithms for:
  - ☀ Nonces (used in authentication protocols)
  - ☀ Session key generation (by the KDC or an end system)
  - ☀ Key generation for the RSA algorithm
- 🌐 Two requirements: **randomness** and **unpredictability**.

# Pseudorandom Numbers

- 🌐 True random numbers are hard to come by.
- 🌐 Cryptographic applications typically use **algorithmic techniques** for random number generation.
- 🌐 These algorithms are deterministic and therefore produce sequence of numbers that are not statistically random.
- 🌐 If the algorithm is good, the resulting sequences will pass reasonable tests for randomness.
- 🌐 Such numbers are often referred to as **pseudorandom numbers**.

# The Linear Congruential Method

$m$	the modulus	$m > 0$
$a$	the multiplier	$0 \leq a < m$
$c$	the increment	$0 \leq c < m$
$X_0$	the starting value (seed)	$0 \leq X_0 < m$

- 🌐 Iterative equation:  $X_{n+1} = (aX_n + c) \bmod m$
- 🌐 Larger values of  $m$  imply higher potential for a long period.
- 🌐 For example,  $X_{n+1} = (7^5 X_n) \bmod (2^{31} - 1)$  has a period of  $2^{31} - 2$ .
- 🌐 What are the weakness and the remedy?

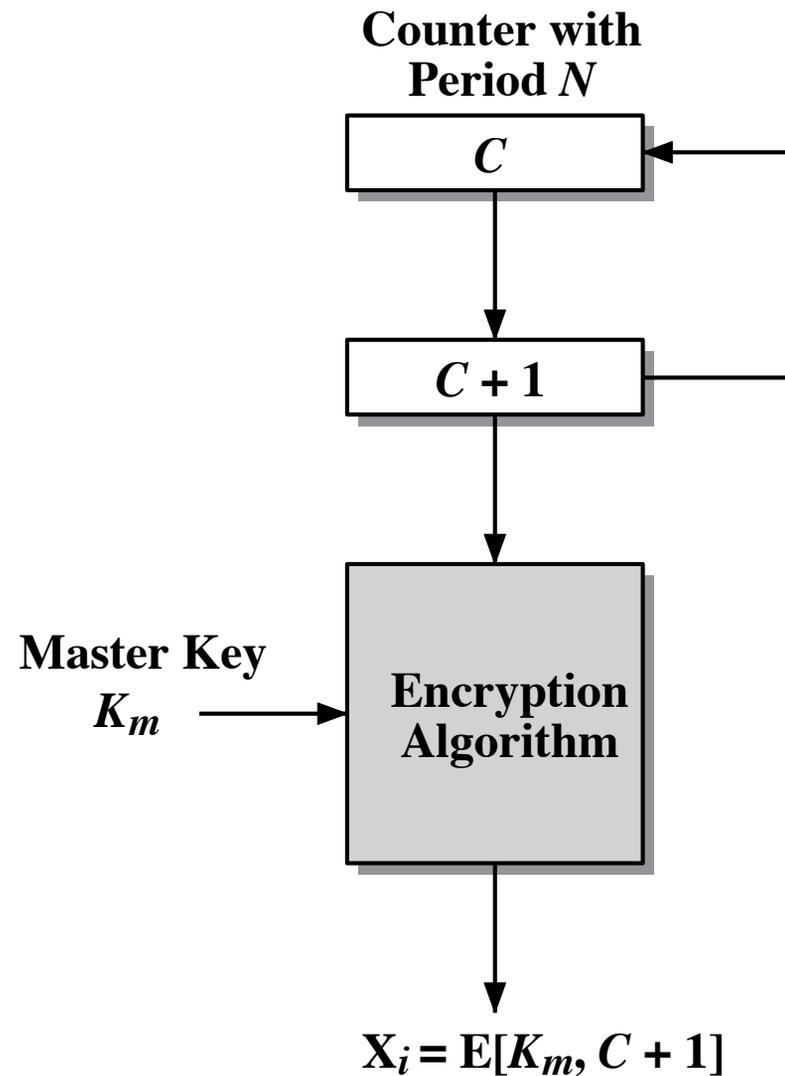

# Cryptographical Generation

- 🌐 **Cyclic encryption:** use an arbitrary block cipher. Full-period generating functions are easily obtained.
- 🌐 **DES Output Feedback Mode:** the successive 64-bit outputs constitute a sequence of pseudorandom numbers.
- 🌐 **ANSI X9.17 Pseudorandom number generator (PRNG):** make use of triple DES. Employed in financial security applications and PGP.

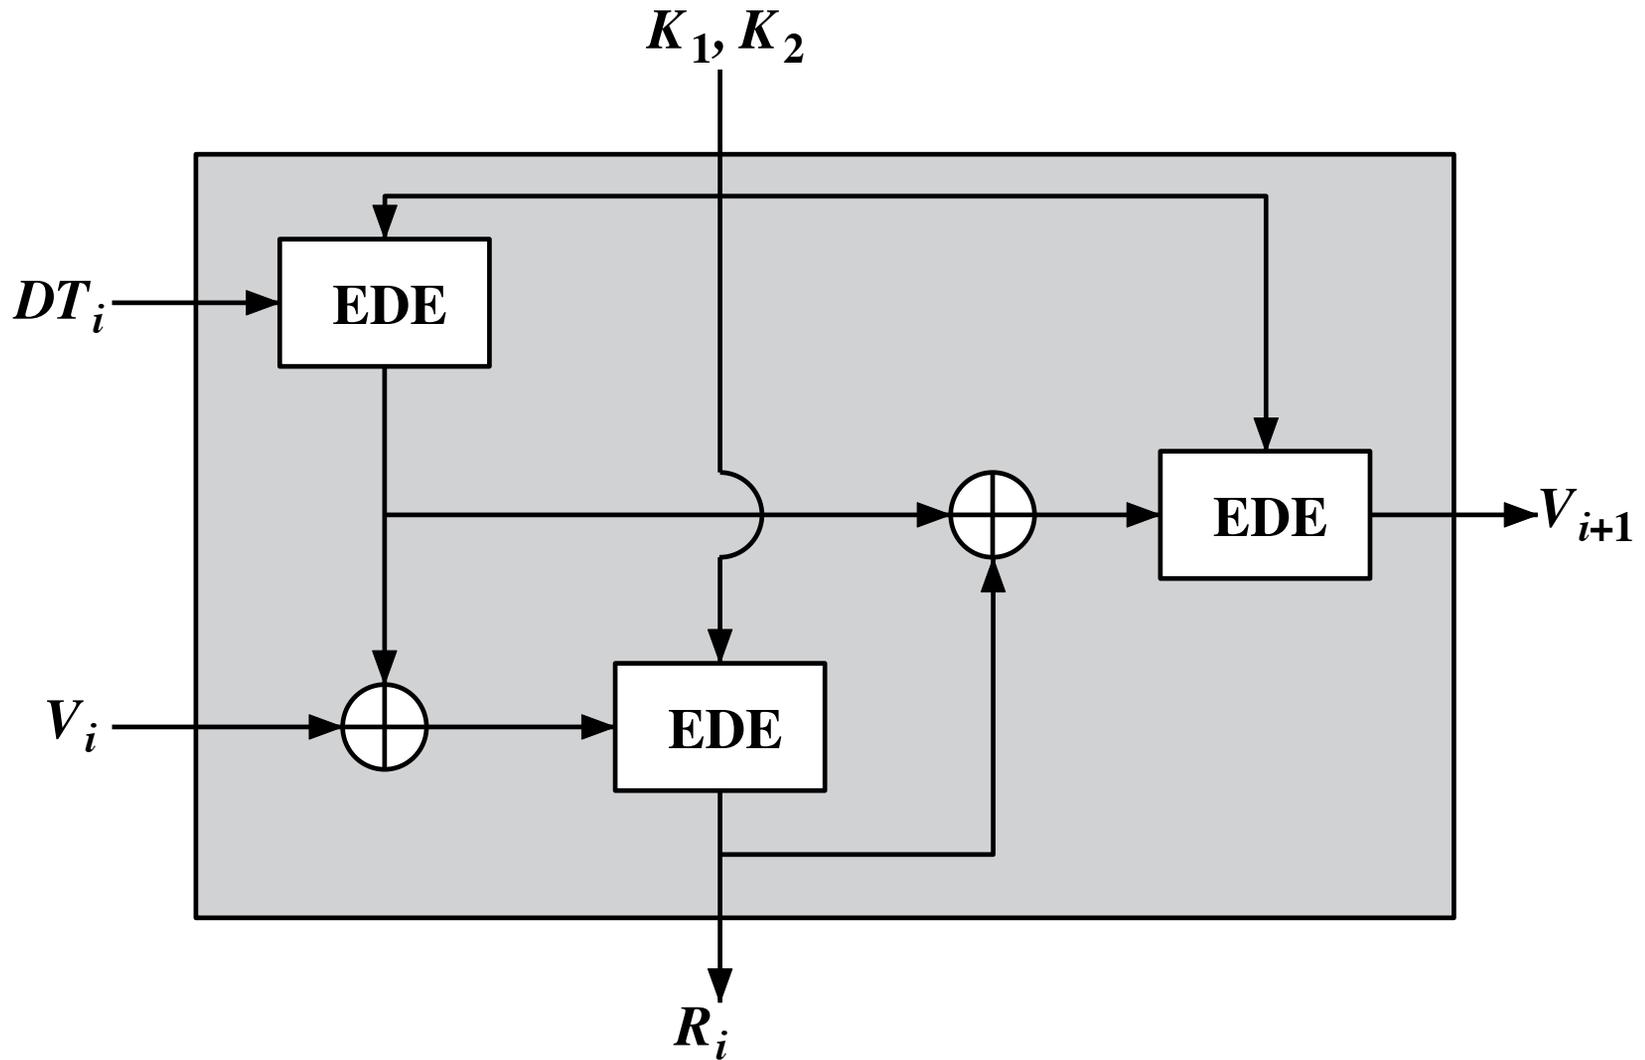

# Pseudorandom Number Generation

# ANSI X9.17 PRNG

Source: Figure 7.14, Stallings 2006

# The Blum Blum Shub (BBS) Generator

- Choose two large prime numbers  $p$  and  $q$  such that  $p \equiv q \equiv 3 \pmod{4}$ . Let  $n = p \times q$ .
- Choose a random number  $s$  relatively prime to  $n$ .
- Bit sequence generating algorithm:

$$X_0 = s^2 \pmod{n}$$

**for**  $i = 1$  **to**  $\infty$

$$X_i = (X_{i-1})^2 \pmod{n}$$

$$B_i = X_i \pmod{2}$$

- The BBS generator passes the **next-bit test**.

# Example Operation of BBS Generator

$i$	$X_i$	$B_i$
0	20749	
1	143135	1
2	177671	1
3	97048	0
4	89992	0
5	174051	1
6	80649	1
7	45663	1
8	69442	0
9	186894	0
10	177046	0

$i$	$X_i$	$B_i$
11	137922	0
12	123175	1
13	8630	0
14	114386	0
15	14863	1
16	133015	1
17	106065	1
18	45870	0
19	137171	1
20	48060	0
