- We say a nonzero integer b divides another integer a, denoted as b|a, if a = mb for some integer m.
- When an integer a is divided by a positive integer n, we get a unique integer quotient q and a unique integer remainder r such that

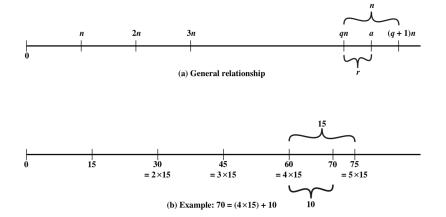

$$a = qn + r$$
 $0 \le r < n, q = \lfloor a/n \rfloor.$

The remainder r is also referred to as a residue.

Essence of the Euclidean Algorithm

- Given two integers a and b such that $a \ge b > 0$.
- Let a = qb + r, where $0 \le r < b$.
- 😚 There are two cases:

***** If r = 0, then we know immediately gcd(a, b) = b and stop.

- If r \neq 0, repeat the steps above with b as a and r as b.
- In both cases, the equality gcd(a, b) = gcd(b, r) holds.
 - Sonsider a = qb + r.
 - Since gcd(b, r)|b and gcd(b, r)|r, we have gcd(b, r)|a.
 - So both gcd(b, r)|a and gcd(b, r)|b; so, $gcd(b, r) \leq gcd(a, b)$.
 - Sonsider r = a qb.
 - Since gcd(a, b)|a, and gcd(a, b)|b, we have gcd(a, b)|r.
 - $ilde{>}$ Both gcd(a, b)|b and gcd(a, b)|r; so, $gcd(a, b) \leq gcd(b, r)$.

Yih-Kuen Tsay (IM.NTU)

Information Security 2013

Modular Arithmetic

The remainder *r* from dividing *a* by n (> 0) is usually denoted by "*a* mod *n*".

$$a = qn + (a \mod n)$$
 $q = \lfloor a/n \rfloor$.

11 mod 7 = 4 (because
$$11 = 1 \times 7 + 4$$
).

 $-11 \mod 7 = 3$ (because $-11 = -2 \times 7 + 3$).

Yih-Kuen Tsay (IM.NTU)

Basic Number Theory and Finite Fields

Information Security 2013

Congruence Modulo *N*

- Two integers a and b are congruent modulo n (n > 0), denoted as $a \equiv b \pmod{n}$, if $a \mod n = b \mod n$.
- The positive integer n is called the modulus of the congruence relation.
- If $a \equiv 0$ (mod n), then n|a; and vice versa.
- If $a \equiv b \pmod{n}$, then n|(a b); and vice versa.

Modular Arithmetic Operations

Properties:

$$((a \mod n) + (b \mod n)) \mod n = (a+b) \mod n$$
$$((a \mod n) - (b \mod n)) \mod n = (a-b) \mod n$$
$$((a \mod n) \times (b \mod n)) \mod n = (a \times b) \mod n$$

Applications:

$$\begin{array}{rcl} 11^7 \pmod{13} \\ \equiv & (11 \times 11^2 \times 11^4) \pmod{13} \\ \equiv & (11 \pmod{13}) \times (11^2 \pmod{13}) \times (11^4 \pmod{13}) \\ \equiv & (11 \pmod{13}) \times (4 \pmod{13}) \times (3 \pmod{13}) \\ \equiv & (11 \times 4 \times 3) \pmod{13} \\ \equiv & 2 \pmod{13} \end{array}$$

Residue Classes

11 / 41

Let Z_n denote the set of nonnegative integers less than n:

$$Z_n = \{0, 1, 2, \cdots, (n-1)\}.$$

This is referred to as the set of residues, or *residue classes*, modulo *n*. Each integer *r* in Z_n represents a residue class [r], where

$$[r] = \{a: a \text{ is an integer}, a \equiv r \pmod{n}\}.$$

For example, if the modulus is 4, then

$$[1] = \{\cdots, -7, -3, 1, 5, 9, 13, \cdots\}.$$

Principles of Modular Arithmetic

If $(a + b) \equiv (a + c) \pmod{n}$, then $b \equiv c \pmod{n}$. If $(a \times b) \equiv (a \times c) \pmod{n}$, then $b \equiv c \pmod{n}$, only when a is relatively prime to n.

 $(6 \times 3) \equiv (6 \times 7) \pmod{8}$, but $3 \not\equiv 7 \pmod{8}$.

Yih-Kuen Tsay (IM.NTU)

Basic Number Theory and Finite Fields

Modular Arithmetic in Z_n

Property	Expression
Commutative Laws	$(w + x) \mod n = (x + w) \mod n$ $(w \times x) \mod n = (x \times w) \mod n$
Associative Laws	$[(w+x)+y] \mod n = [w+(x+y)] \mod n$ $[(w\times x)\times y] \mod n = [w\times (x\times y)] \mod n$
Distributive Law	$[w \times (x + y)] \mod n = [(w \times x) + (w \times y)] \mod n$
Identities	$(0 + w) \mod n = w \mod n$ $(1 \times w) \mod n = w \mod n$
Additive Inverse (-w)	For each $w \in \mathbb{Z}_n$, there exists a <i>z</i> such that $w + z \equiv 0 \mod n$

Finding the Multiplicative Inverse

$$\begin{array}{ll} \textit{EXTENDED EUCLID}(a,b):\\ 1. & (X_1,Y_1,R_1) \leftarrow (1,0,a); (X_2,Y_2,R_2) \leftarrow (0,1,b)\\ 2. & \text{if } R_2 = 0 \text{ then return } R_1 = \gcd(a,b); \text{ no inverse}\\ 3. & \text{if } R_2 = 1 \text{ then return } R_2 = \gcd(a,b); Y_2 = b^{-1} \pmod{a}\\ 4. & Q = \lfloor R_1/R_2 \rfloor\\ 5. & (X,Y,R) \leftarrow (X_1 - QX_2,Y_1 - QY_2,R_1 - QR_2)\\ 6. & (X_1,Y_1,R_1) \leftarrow (X_2,Y_2,R_2)\\ 7. & (X_2,Y_2,R_2) \leftarrow (X,Y,R)\\ 8. & \gcd{2} \end{array}$$

• Invariants: $aX_1 + bY_1 = R_1$ and $aX_2 + bY_2 = R_2$.

If gcd(a, b) = 1, then Y₂ equals the multiplicative inverse of b modulo a when the algorithm terminates. $aX_2 + bY_2 = R_2 = 1 → bY_2 = 1 - aX_2 → bY_2 \equiv 1 \mod a.$

Cyclic Groups

• Let a^n denote $a \cdot a \cdot \cdots \cdot a$ with $n \ (\geq 0)$ occurrences of a. Formally,

$$a^n = \left\{ egin{array}{cc} e & ext{if } n=0 \ a \cdot a^{n-1} & ext{if } n>0 \end{array}
ight.$$

- A group G is cyclic if, for every b in G, $b = a^n$ for a fixed a in G and some integer $n \ge 0$.
- The fixed element a is said to generate G and is called the generator of G.

19 / 41

- Solution $\mathcal{Z}_p = \{0, 1, 2, \cdots, (p-1)\}$ where p is a prime.
- For each w ∈ Z_p, w ≠ 0, there exists a z ∈ Z_p such that w × z ≡ 1 (mod p).
- The element z is called the multiplicative inverse of w.
- For any prime p, $(Z_p, +, \times)$ is a finite field of order p, denoted GF(p).

イロト 不得下 イヨト イヨト 二日

Modular Polynomial Arithmetic

• Let S denote the set of all polynomials of degree n - 1 or less over the field Z_p with the form

$$f(x) = a_{n-1}x^{n-1} + a_{n-2}x^{n-2} + \cdots + a_1x + a_0$$

where each a_i takes on a value in Z_p . Arithmetic on the coefficients is performed modulo p.

- If multiplication results in a polynomial of degree greater than n-1, then the polynomial is reduced modulo some irreducible polynomial of degree n.
- Each such S is a finite field; every nonzero element a in S has a multiplicative inverse a^{-1} such that $a \times a^{-1} = 1$.
- Such an S is denoted as $GF(2^n)$ when p = 2.

Yih-Kuen Tsay (IM.NTU)

Irreducible Polynomials

30 / 41

- A polynomial f(x) is *irreducible* if f(x) cannot be expressed as a product of two polynomials with degrees lower than that of f(x).
- Irreducible polynomials play a role analogous to that of primes.
- The AES algorithm uses the finite field GF(2⁸) with the following irreducible polynomial modulus

$$x^8 + x^4 + x^3 + x + 1.$$

Extended Euclid's Algorithm for $GF(p^n)$

EXTENDED EUCLID(a(x), b(x)): $[V_1(x), W_1(x), R_1(x)] \leftarrow [1, 0, a(x)]; [V_2(x), W_2(x), R_2(x)] \leftarrow [0, 1, b(x)]$ 1. if $R_2(x) = 0$ then return $R_1(x) = \gcd(a(x), b(x))$; no inverse 2. 3. if $R_2(x) = 1$ then return $R_2(x) = \gcd(a(x), b(x)); W_2(x) = b^{-1}(x) \pmod{a(x)}$ Q(x) = the quotient of $R_1(x)/R_2(x)$ 4. 5 [V(x), W(x), R(x)] $\leftarrow [V_1(x) - Q(x)V_2(x), W_1(x) - Q(x)W_2(x), R_1(x) - Q(x)R_2(x)]$ 6. $[V_1(x), W_1(x), R_1(x)] \leftarrow [V_2(x), W_2(x), R_2(x)]$ 7. $[V_2(x), W_2(x), R_2(x)] \leftarrow [V(x), W(x), R(x)]$ goto 2 8.

- Invariants: $a(x)V_1(x) + b(x)W_1(x) = R_1(x)$ and $a(x)V_2(x) + b(x)W_2(x) = R_2(x)$.
- If gcd(a(x), b(x)) = 1, then $W_2(x)$ equals the multiplicative inverse of b(x) modulo a(x) when the algorithm terminates.

A Run of Extended Euclid

The following run finds the multiplicative inverse of $x^7 + x + 1$ in GF(2⁸) with $x^8 + x^4 + x^3 + x + 1$ as the irreducible polynomial modulus; the result is x^7 .

Initialization	$a(x) = x^{8} + x^{4} + x^{3} + x + 1; v_{-1}(x) = 1; w_{-1}(x) = 0$
	$b(x) = x^7 + x + 1; v_0(x) = 0; w_0(x) = 1$
Iteration 1	$q_1(x) = x; r_1(x) = x^4 + x^3 + x^2 + 1$
	$v_1(x) = 1; w_1(x) = x$
Iteration 2	$q_2(x) = x^3 + x^2 + 1; r_2(x) = x$
	$v_2(x) = x^3 + x^2 + 1; w_2(x) = x^4 + x^3 + x + 1$
Iteration 3	$q_3(x) = x^3 + x^2 + x; r_3(x) = 1$
	$v_3(x) = x^6 + x^2 + x + 1; w_3(x) = x^7$
Iteration 4	$q_4(x) = x; r_4(x) = 0$
	$v_4(x) = x^7 + x + 1; w_4(x) = x^8 + x^4 + x^3 + x + 1$
Result	$d(x) = r_3(x) = \gcd(a(x), b(x)) = 1$
	$w(x) = w_3(x) = (x^7 + x + 1)^{-1} \mod (x^8 + x^4 + x^3 + x + 1) = x^7$

Bytes and Polynomials in $GF(2^8)$

35 / 41

- 📀 In the AES algorithm, the basic unit for processing is a byte.
- A byte $b_7b_6b_5b_4b_3b_2b_1b_0$ is interpreted as an element of the finite field $GF(2^8)$ using the polynomial representation:

$$b_7x^7 + b_6x^6 + b_5x^5 + b_4x^4 + b_3x^3 + b_2x^2 + b_1x + b_0 = \sum_{i=0}^7 b_ix^i.$$

For example, 01100011 identifies $x^6 + x^5 + x + 1$.

Addition in $GF(2^8)$

The addition of two polynomials in the finite field GF(2⁸) is achieved by adding (modulo 2) the coefficients of the corresponding powers.

polnomial representation: $(x^{6} + x^{4} + x^{2} + x + 1) + (x^{7} + x + 1) = x^{7} + x^{6} + x^{4} + x^{2}$ binary representation: $01010111 \oplus 10000011 = 11010100$ hexadecimal representation: $\{57\} \oplus \{83\} = \{D4\}$

Information Secur

Multiplication in GF(2⁸)

• Let f(x) be $b_7x^7 + b_6x^6 + b_5x^5 + b_4x^4 + b_3x^3 + b_2x^2 + b_1x + b_0$. • Multiply f(x) by x, we have

$$f(x) \times x = b_7 x^8 + b_6 x^7 + b_5 x^6 + b_4 x^5 + b_3 x^4 + b_2 x^3 + b_1 x^2 + b_0 x \mod m(x)$$

Again, for the AES algorithm,

$$m(x) = x^8 + x^4 + x^3 + x + 1.$$

When $b_7 = 0$, the result is already in the reduced form.

Yih-Kuen Tsay (IM.NTU)

Basic Number Theory and Finite Fields

Information Security 2013

Multiplication in $GF(2^8)$ (cont.)

• When
$$b_7 = 1$$
:

$$f(x) \times x$$

$$= (x^{7} + b_{6}x^{6} + b_{5}x^{5} + b_{4}x^{4} + b_{3}x^{3} + b_{2}x^{2} + b_{1}x + b_{0}) \times x \mod m(x)$$

$$= x^{8} + b_{6}x^{7} + b_{5}x^{6} + b_{4}x^{5} + b_{3}x^{4} + b_{2}x^{3} + b_{1}x^{2} + b_{0}x \mod m(x)$$

$$= (b_{6}x^{7} + b_{5}x^{6} + b_{4}x^{5} + b_{3}x^{4} + b_{2}x^{3} + b_{1}x^{2} + b_{0}x) + (x^{4} + x^{3} + x + 1) \mod m(x)$$

Note:
$$x^8 \mod m(x) = m(x) - x^8 = x^4 + x^3 + x + 1$$
.
To summarize in binary representation,

$$f(x) \times x = \begin{cases} (b_6 b_5 b_4 b_3 b_2 b_1 b_0 0) & \text{if } b_7 = 0 \\ (b_6 b_5 b_4 b_3 b_2 b_1 b_0 0) \oplus (00011011) & \text{if } b_7 = 1 \end{cases}$$

Repeat the above to get multiplications by x^2 , x^3 , etc.

Generators for Finite Fields

39 / 41

A generator for $GF(2^3)$ using $f(x) = x^3 + x + 1$ (irreducible):

Power Representation	Polynomial Representation	Binary Representation	Decimal (Hex) Representation	
0	0	000	0	
$g^0 (= g^7)$	1	001	1	
g^1	g	010	2	
<i>g</i> ²	g^2	100	4	
<i>g</i> ³	<i>g</i> + 1	011	3	
g ⁴	$g^2 + g$	110	6	
g ⁵	$g^2 + g + 1$	111	7	
g^6	$g^2 + 1$	101	5	

Source: Table 4.9, Stallings 2014

Note: $f(g) = g^3 + g + 1 = 0$, $g^3 = -g - 1 = g + 1$, $g^4 = g(g^3) = g(g + 1) = g^2 + g$, etc.
