

# Software Verification: Hoare Logic and Predicate Transformers

(Based on [Apt and Olderog 1991; Dijkstra 1976; Gries 1981; Hoare 1969; Kleymann 1999; Sethi 1996])

Yih-Kuen Tsay

Department of Information Management National Taiwan University

# **An Axiomatic View of Programs**

- The properties of a program can, in principle, be found out from its text by means of purely *deductive reasoning*.
- The deductive reasoning involves the application of valid inference rules to a set of valid axioms.
- The choice of axioms will depend on the choice of programming languages.
- We shall introduce such an axiomatic approach, called the Hoare logic, to program correctness.

#### Assertions

- When executed, a program will evolve through different states, which are essentially a mapping of the program variables to values in their respective domains.
- 😚 To reason about correctness of a program, we inevitably need to talk about its states.
- An assertion is a precise statement about the state of a program.
- Most interesting assertions can be expressed in a *first-order* language.

#### Pre and Post-conditions

- The behavior of a "structured" (single-entry/single-exit) program statement can be characterized by attaching assertions at the entry and the exit of the statement.
- For a statement S, this is conveniently expressed as a so-called *Hoare triple*, denoted  $\{P\}$  S  $\{Q\}$ , where
  - P is called the pre-condition and
  - Q is called the post-condition of S.

## Interpretations of a Hoare Triple

- A Hoare triple  $\{P\}$  S  $\{Q\}$  may be interpreted in two different ways:
  - Partial Correctness: if the execution of S starts in a state satisfying P and terminates, then it results in a state satisfying Q.
  - Total Correctness: if the execution of S starts in a state satisfying P, then it will terminate and result in a state satisfying Q.

Note: sometimes we write  $\langle P \rangle$  *S*  $\langle Q \rangle$  when total correctness is intended.

# **Pre and Post-Conditions for Specification**

Find an integer approximate to the square root of another integer *n*:

$$\{0 \le n\}$$
 ?  $\{d^2 \le n < (d+1)^2\}$ 

or slightly better (clearer about what can be changed)

$$\{0 \le n\} \ d := ? \{d^2 \le n < (d+1)^2\}$$

- Find the index of value x in an array b:
  - $\{x \in b[0..n-1]\}$  ?  $\{0 \le i < n \land x = b[i]\}$
  - \*  $\{0 < n\}$  ?  $\{(0 \le i < n \land x = b[i]) \lor (i = n \land x \notin b[0..n 1])\}$

Note: there are other ways to stipulate which variables are to be changed and which are not.

## A Little Bit of History

The following seminal paper started it all:

C.A.R. Hoare. An axiomatic basis for computer programs. CACM, 12(8):576-580, 1969.

- Interpretation: partial correctness
- Provided axioms and proof rules

Note: R.W. Floyd did something similar for flowcharts earlier in 1967, which was also a precursor of "proof outline" (a program fully annotated with assertions).

## The Assignment Statement

😚 Syntax:

$$x := E$$

- Meaning: execution of the assignment x := E (read as "x becomes E'') evaluates E and stores the result in variable x.
- We will assume that expression E in x := E has no side-effect (i.e., does not change the value of any variable).
- Which of the following two Hoare triples is correct about the assignment x := E?
  - P  $\{P\} x := E \{P[E/x]\}$
  - $(Q[E/x]) \times = E \{Q\}$

Note: *E* is essentially a first-order term.

# **Some Hoare Triples for Assignments**

- $\{x+1>5\}\ x:=x+1\ \{x>5\}$

## **Axiom of the Assignment Statement**

$$\frac{}{\{Q[E/x]\} \ x := E \ \{Q\}} (Assignment)$$

#### Why is this so?

- Let s be the state before x := E and s' the state after.
- $\P$  So, s' = s[x := E] assuming E has no side-effect.
- $\bigcirc$  Q[E/x] holds in s if and only if Q holds in s', because
  - $\stackrel{\text{$\rlap$}{$\rlap$}}{}$  every variable, except x, in Q[E/x] and Q has the same value in s and s', and
  - Q[E/x] has every x in Q replaced by E, while Q has every x evaluated to E in s' (= s[x := E]).

# The Multiple Assignment Statement

Syntax:

$$x_1, x_2, \cdots, x_n := E_1, E_2, \cdots, E_n$$

where  $x_i$ 's are distinct variables.

- Meaning: execution of the multiple assignment evaluates all  $E_i$ 's and stores the results in the corresponding variables  $x_i$ 's.
- Examples:
  - i,j := 0,0 (initialize i and j to 0)
  - $\stackrel{*}{=} x, y := y, x$  (swap x and y)
  - $ilde{*} \; g,p:=g+1,p-1$  (increment g by 1, while decrement p by 1)
  - i, x := i + 1, x + i (increment i by 1 and x by i)

# Some Hoare Triples for Multi-assignments

Swapping two values

$${x < y} x, y := y, x {y < x}$$

Number of games in a tournament

$${g+p=n}\ g, p:=g+1, p-1\ {g+p=n}$$

🕝 Taking a sum

$$\{x + i = 1 + 2 + \dots + (i + 1 - 1)\}\$$
  

$$i, x := i + 1, x + i$$
  

$$\{x = 1 + 2 + \dots + (i - 1)\}\$$

#### Simultaneous Substitution

- P[E/x] can be naturally extended to allow E to be a list  $E_1, E_2, \dots, E_n$  and x to be  $x_1, x_2, \dots, x_n$ , all of which are distinct variables.
- P[E/x] is then the result of simultaneously replaying  $x_1, x_2, \dots, x_n$  with the corresponding expressions  $E_1, E_2, \dots, E_n$ ; enclose  $E_i$ 's in parentheses if necessary.
- Examples:
  - (x < y)[y, x/x, y] = (y < x)
  - \* (g + p = n)[g + 1, p 1/g, p] = ((g + 1) + (p 1) = n) = (g + p = n)
  - \*  $(x = 1 + 2 + \dots + (i 1))[i + 1, x + i/i, x]$ =  $((x + i) = 1 + 2 + \dots + ((i + 1) - 1))$ =  $(x + i = 1 + 2 + \dots + ((i + 1) - 1))$

# **Axiom of the Multiple Assignment**

Syntax:

$$x_1, x_2, \cdots, x_n := E_1, E_2, \cdots, E_n$$

where  $x_i$ 's are distinct variables.

Axiom:

$$\overline{\{Q[E_1,\cdots,E_n/x_1,\cdots,x_n]\}\ x_1,\cdots,x_n:=E_1,\cdots,E_n\ \{Q\}}$$
 (Assign.)

# **Assignment to an Array Entry**

Syntax:

$$b[i] := E$$

Notation for an altered array: (b; i : E) denotes the array that is identical to b, except that entry i stores the value of E.

$$(b; i : E)[j] = \begin{cases} E & \text{if } i = j \\ b[j] & \text{if } i \neq j \end{cases}$$

Axiom:

$$\frac{1}{\{Q[(b;i:E)/b]\}\ b[i]:=E\ \{Q\}} (Assignment)$$

## Pre and Post-condition of a Loop

- A precondition just before a loop can capture the conditions for executing the loop.
- An assertion just within a loop body can capture the conditions for staying in the loop.
- A postcondition just after a loop can capture the conditions upon leaving the loop.

## A Simple Example

```
\{x \ge 0 \land y > 0\}

while x \ge y do

\{x \ge 0 \land y > 0 \land x \ge y\}

x := x - y

od

\{x \ge 0 \land y > 0 \land x \not\ge y\}

// or

\{x \ge 0 \land y > 0 \land x < y\}
```

## More about the Example

We can say more about the program.

```
// may assume x, y := m, n here for some m \ge 0 and n > 0 \{x \ge 0 \land y > 0 \land (x \equiv m \pmod{y})\} while x \ge y do x := x - y od \{x \ge 0 \land y > 0 \land (x \equiv m \pmod{y}) \land x < y\}
```

Note: repeated subtraction is a way to implement the integer division. So, the program is taking the residue of x divided by y.

# A Simple Programming Language

To study inference rules of Hoare logic, we consider a simple programming language with the following syntax for statements:

```
S ::=  skip

| x := E

| S_1; S_2

|  if B then S fi

|  if B then S_1 else S_2 fi

|  while B do S od
```

#### **Proof Rules**

"if *B* then *S* fi" can be treated as "if *B* then *S* else skip fi" or directly with the following rule:

$$\frac{\{P \land B\} \ S \ \{Q\} \qquad P \land \neg B \to Q}{\{P\} \ \text{if} \ B \ \text{then} \ S \ \text{fi} \ \{Q\}}$$

 $\{P\}$  if B then  $S_1$  else  $S_2$  fi  $\{Q\}$ 

(If-Then)

#### **Proof Rules (cont.)**

$$\frac{\{P \land B\} \ S \ \{P\}}{\{P\} \ \text{while } B \ \text{do} \ S \ \text{od} \ \{P \land \neg B\}}$$

$$\frac{P \rightarrow P' \qquad \{P'\} \ S \ \{Q'\} \qquad Q' \rightarrow Q}{\{P\} \ S \ \{Q\}}$$
(Consequence)

Note: with a suitable notion of validity, the set of proof rules up to now can be shown to be sound and (relatively) complete for programs that use only the considered constructs.

## Some Auxiliary Rules

$$\frac{P \to P' \qquad \{P'\} \ S \ \{Q\}}{\{P\} \ S \ \{Q\}}$$

$$\frac{\{P\}\ S\ \{Q'\}\qquad Q'\to Q}{\{P\}\ S\ \{Q\}}$$

$$({\sf Weakening\ Postcondition})$$

$$\frac{\{P_1\} \ S \ \{Q_1\} \qquad \{P_2\} \ S \ \{Q_2\}}{\{P_1 \land P_2\} \ S \ \{Q_1 \land Q_2\}}$$

$$\frac{\{P_1\} \ S \ \{Q_1\} \qquad \{P_2\} \ S \ \{Q_2\}}{\{P_1 \lor P_2\} \ S \ \{Q_1 \lor Q_2\}}$$

Note: these rules provide more convenience, but do not actually add deductive power.

#### **Invariants**

- An invariant at some point of a program is an assertion that holds whenever execution of the program reaches that point.
- Assertion P in the rule for a while loop is called a loop invariant of the while loop.
- An assertion is called an invariant of an operation (a segment of code) if, assumed true before execution of the operation, the assertion remains true after execution of the operation.
- Invariants are a bridge between the static text of a program and its dynamic computation.

#### **Program Annotation**

• Inserting assertions/invariants in a program as comments helps understanding of the program.

```
 \{x \ge 0 \land y > 0 \land (x \equiv m \pmod{y})\}  while x \ge y do  \{x \ge 0 \land y > 0 \land x \ge y \land (x \equiv m \pmod{y})\}   x := x - y   \{y > 0 \land x \ge 0 \land (x \equiv m \pmod{y})\}  od  \{x \ge 0 \land y > 0 \land (x \equiv m \pmod{y}) \land x < y\}
```

- A correct annotation of a program can be seen as a partial proof outline for the program.
- Boolean assertions can also be used as an aid to program testing.

## **An Annotated Program**

```
\{x \geq 0 \land y \geq 0 \land gcd(x, y) = gcd(m, n)\}
while x \neq 0 and y \neq 0 do
    \{x \geq 0 \land y \geq 0 \land gcd(x, y) = gcd(m, n)\}
    if x < y then x, y := y, x fi;
    \{x > y \land y > 0 \land gcd(x, y) = gcd(m, n)\}\
    x := x - y
    \{x > 0 \land y > 0 \land gcd(x, y) = gcd(m, n)\}
od
\{(x=0 \land v > 0 \land v = gcd(x,v) = gcd(m,n)\} \lor \}
 \{x > 0 \land y = 0 \land x = gcd(x, y) = gcd(m, n)\}
```

Note: m and n are two arbitrary non-negative integers, at least one of which is nonzero.

#### **Total Correctness: Termination**

- All inference rules introduced so far, except the while rule, work for total correctness.
- Below is a rule for the total correctness of the **while** statement:

$$\{P \wedge B\} S \{P\} \qquad \{P \wedge B \wedge t = Z\} S \{t < Z\} \qquad P \rightarrow (t \ge 0)$$

$$\{P\}$$
 while  $B$  do  $S$  od  $\{P \land \neg B\}$ 

where t is an integer-valued expression (state function) and Z is a "rigid" variable that does not occur in P, B, t, or S.

 $\bigcirc$  The above function t is called a rank (or variant) function.

# **Termination of a Simple Program**

$$g,p:=0,n;\quad //\ n\geq 1$$
 while  $p\geq 2$  do  $g,p:=g+1,p-1$  od

- ${f \odot}$  Loop Invariant:  $(g+p=n) \wedge (p\geq 1)$
- Rank (Variant) Function: *p*
- ightharpoonup The loop terminates when  $p=1\;(p\geq 1\land p\ngeq 2)$ .

#### **Well-Founded Sets**

- lacktriangledown A binary relation  $\preceq \subseteq A \times A$  is a **partial order** if it is
  - $\circledast$  reflexive:  $\forall x \in A(x \leq x)$ ,
  - $ilde{*}$  transitive:  $\forall x,y,z\in A((x\preceq y\wedge y\preceq z) o x\preceq z)$ , and
  - $\red$  antisymmetric:  $\forall x,y \in A((x \leq y \land y \leq x) \rightarrow x = y).$
- A partially ordered set (W, ≤) is well-founded if there is no infinite decreasing chain  $x_1 \succ x_2 \succ x_3 \succ \cdots$  of elements from W. (Note: "x \subseteq y" means "y ≤ x \land y \neq x".)
- Examples:
  - $\stackrel{*}{=} (Z_{\geq 0}, \leq)$
  - $(Z_{\geq 0} \times Z_{\geq 0}, \leq)$ , where  $(x_1, y_1) \leq (x_2, y_2)$  if  $(x_1 < x_2) \vee (x_1 = x_2 \wedge y_1 \leq y_2)$

## **Termination by Well-Founded Induction**

Below is a more general rule for the total correctness of the **while** statement:

where  $(W, \preceq)$  is a well-founded set,  $\delta$  is a state function, and D is a "rigid" variable ranged over W that does not occur in P, B,  $\delta$ , or S.

#### Nondeterminism

Syntax of the Alternative Statement:

$$\begin{array}{ccc}
\mathbf{if} & B_1 \to S_1 \\
\parallel B_2 \to S_2 \\
\dots \\
\parallel B_n \to S_n \\
\mathbf{fi}
\end{array}$$

Each of the " $B_i \rightarrow S_i$ " s is called a guarded command, where  $B_i$  is the guard of the command and  $S_i$  the body.

- Semantic:
  - 1. One of the guarded commands, whose guard evaluates to true, is nondeterministically selected and its body executed.
  - 2. If none of the guards evaluates to true, then the execution aborts.

#### **Rule for the Alternative Statement**

The Alternative Statement:

$$\begin{array}{c} \textbf{if} \ B_1 \rightarrow S_1 \\ \parallel B_2 \rightarrow S_2 \\ \cdots \\ \parallel B_n \rightarrow S_n \\ \textbf{fi} \end{array}$$

Inference rule:

$$\frac{P \to B_1 \lor \dots \lor B_n \qquad \{P \land B_i\} \ S_i \ \{Q\}, \text{ for } 1 \le i \le n}{\{P\} \ \text{if } B_1 \to S_1 \| \dots \| \ B_n \to S_n \ \text{fi} \ \{Q\}}$$

# The Coffee Can Problem as a Program

```
\begin{array}{l} B,\,W\,:=\,m,\,n;\,\,\,//\,\,m>0\,\wedge\,n>0\\ \textbf{while}\,\,B+W\geq 2\,\,\textbf{do}\\ &\textbf{if}\,\,B\geq 0\,\wedge\,W>1\,\rightarrow\,B,\,W\,:=\,B+1,\,W-2\,\,\,\,//\,\,\text{same color}\\ &\parallel B>1\,\wedge\,W\geq 0\,\rightarrow\,B,\,W\,:=\,B-1,\,W\,\,\,\,//\,\,\text{same color}\\ &\parallel B>0\,\wedge\,W>0\,\rightarrow\,B,\,W\,:=\,B-1,\,W\,\,\,\,//\,\,\text{different colors}\\ &\textbf{fi} \end{array}
```

- od
  - ♦ Loop Invariant:  $W \equiv n \pmod{2}$  (and  $B + W \ge 1$ )
  - Variant (Rank) Function: B + W
  - igoplus The loop terminates when B+W=1.

#### **Predicate Transformers: Basic Idea**

- The execution of a sequential program, if terminating, transforms the initial state into some final state.
- If, for any given postcondition, we know the weakest precondition that guarantees termination of the program in a state satisfying the postcondition,

then we have fully understood the meaning of the program.

Note: the weakest precondition is the weakest in the sense that it identifies all the desired initial states and nothing else.

## The Predicate Transformer wp

- ullet For a program S and a predicate (or an assertion) Q, let wp(S,Q) denote the aformentioned weakest precondition.
- 😚 Therefore, we can see a program as a predicate transformer  $wp(S, \cdot)$ , transforming a postcondition Q (a predicate) into its weakest precondition wp(S, Q).
- If the execution of S starts in a state satisfying wp(S, Q), it is guaranteed to terminate and result in a state satisfying Q.

Note: there is a weaker variant of wp, called wlp (weakest liberal precondition), which is defined almost identical to wp except that termination is not guaranteed.

## **Hoare Triples in Terms of** wp

- When total correctness is meant,  $\{P\}$  S  $\{Q\}$  can be understood as saying  $P \Rightarrow wp(S, Q)$ .
- In fact, with a suitable formal definition, wp provides a semantic foundation for the Hoare logic.
- The precondition P here may be as weak as wp(S, Q), but often a stronger and easier-to-find P is all that is needed.

## **Properties of wp**

#### Fundamental Properties (Axioms):

- **Q** Law of the Excluded Miracle:  $wp(S, false) \equiv false$
- **Obstributivity of Conjunction:**  $wp(S, Q_1) \wedge wp(S, Q_2) \equiv wp(S, Q_1 \wedge Q_2)$
- **Distributivity of Disjunction** for deterministic S:  $wp(S, Q_1) \lor wp(S, Q_2) \equiv wp(S, Q_1 \lor Q_2)$

#### Derived Properties:

- Law of Monotonicity: if  $Q_1 \Rightarrow Q_2$ , then  $wp(S, Q_1) \Rightarrow wp(S, Q_2)$
- **Obstributivity of Disjunction** for nondeterministic  $S: wp(S, Q_1) \vee wp(S, Q_2) \Rightarrow wp(S, Q_1 \vee Q_2)$

#### **Predicate Calculation**

- Equivalence is preserved by substituting equals for equals
- Example:

$$(A \lor B) \to C$$

$$\equiv \{A \to B \equiv \neg A \lor B\}$$

$$\neg (A \lor B) \lor C$$

$$\equiv \{\text{de Morgan's law }\}$$

$$(\neg A \land \neg B) \lor C$$

$$\equiv \{\text{distributive law }\}$$

$$(\neg A \lor C) \land (\neg B \lor C)$$

$$\equiv \{A \to B \equiv \neg A \lor B\}$$

$$(A \to C) \land (B \to C)$$

### **Predicate Calculation (cont.)**

- Entailment distributes over conjunction, disjunction, quantification, and the consequence of an implication.
- Example:

$$\forall x(A \to B) \land \forall xA$$

$$\Rightarrow \{ \forall x(A \to B) \Rightarrow (\forall xA \to \forall xB) \}$$

$$(\forall xA \to \forall xB) \land \forall xA$$

$$\equiv (\neg \forall xA \lor \forall xB) \land \forall xA$$

$$\equiv (\neg \forall xA \land \forall xA) \lor (\forall xB \land \forall xA)$$

$$\equiv \{ \neg A \land A \equiv false \}$$

$$false \lor (\forall xB \land \forall xA)$$

$$\equiv \{ false \lor A \equiv A \}$$

$$\forall xB \land \forall xA$$

$$\Rightarrow \forall xB$$

### Some Laws for Predicate Calculation

- Equivalence is commutative and associative
  - $\bullet A \leftrightarrow B \equiv B \leftrightarrow A$
- $igcolumn{ } igcolumn{ } ig$
- $\bigcirc \neg A \land A \equiv false$
- $\bigcirc A \rightarrow B \equiv \neg A \lor B$
- $lacktriangledown A 
  ightarrow false \equiv 
  eg A$

- $\bigcirc A \wedge B \Rightarrow A$

# Some Laws for Predicate Calculation (cont.)

- $\bigcirc$   $\exists x (A \land B) \equiv A \land \exists x B$ , if x is not free in A.

# "Extreme" Programs

- $wp(\mathbf{skip}, Q) \stackrel{\Delta}{=} Q$
- wp(choose  $x, x \in Dom(x)$ )  $\stackrel{\triangle}{=}$  true
- $wp({\bf choose} \ x, Q) \stackrel{\Delta}{=} Q$ , if x is not free in Q
- wp(abort, Q)  $\stackrel{\triangle}{=}$  false

# **The Assignment Statement**

Syntax: x := E

Note: this becomes a multiple assignment, if we view x as a list of distinct variables and E as a list of expressions.

• Semantics:  $wp(x := E, Q) \stackrel{\triangle}{=} Q[E/x]$ .

### **Sequencing**

- Syntax:  $S_1$ ;  $S_2$
- Semantics:  $wp(S_1; S_2, Q) \stackrel{\triangle}{=} wp(S_1, wp(S_2, Q))$ .

### The Alternative Statement

Syntax:

IF: **if** 
$$B_1 \rightarrow S_1$$
  
 $\parallel B_2 \rightarrow S_2$   
 $\cdots$   
 $\parallel B_n \rightarrow S_n$   
**fi**

Semantics:

$$wp(\text{IF}, Q) \triangleq (\exists i : 1 \leq i \leq n : B_i) \\ \land (\forall i : 1 \leq i \leq n : B_i \rightarrow wp(S_i, Q))$$

The case of simple IF:

$$wp(\mathbf{if}\ B \to S\ \mathbf{fi}, Q) \stackrel{\Delta}{=} B \wedge (B \to wp(S, Q))$$

### The Alternative Statement (cont.)

Suppose there exists a predicate *P* such that

- 1.  $P \Rightarrow (\exists i : 1 \leq i \leq n : B_i)$  and
- 2.  $\forall i: 1 \leq i \leq n: P \wedge B_i \Rightarrow wp(S_i, Q)$ .

Then  $P \Rightarrow wp(IF, Q)$ .

Inference rule in the Hoare logic:

$$\frac{P \Rightarrow (\exists i : 1 \le i \le n : B_i) \qquad \forall i : 1 \le i \le n : \{P \land B_i\} \ S_i \ \{Q\}\}}{\{P\} \ \text{IF} : \ \textbf{if} \ B_1 \rightarrow S_1 |\!|\!| \cdots |\!|\!| \ B_n \rightarrow S_n \ \textbf{fi} \ \{Q\}}$$

The case of simple IF:

$$\frac{P \Rightarrow B \qquad \{P \land B\} \ S \ \{Q\}}{\{P\} \ \text{if} \ B \rightarrow S \ \text{fi} \ \{Q\}}$$

### The Iterative Statement

😚 Syntax:

Each of the " $B_i \rightarrow S_i$ "s is a guarded command.

- $\bullet$  Informal description: Choose (nondeterministically) a guard  $B_i$ that evaluates to true and execute the corresponding command  $S_i$ . If none of the guards evaluates to true, then the execution terminates.
- The usual "**while** B **do** S **od**" can be defined as this simple while-loop: "do  $B \rightarrow S$  od".

# The Iterative Statement (cont.)

- **③** Let BB denote  $\exists i : 1 \leq i \leq n : B_i$ , i.e.,  $B_1 \lor B_2 \lor \cdots \lor B_n$ .
- The DO statement is equivalent to

do BB 
$$ightarrow$$
 if  $B_1 
ightarrow S_1$ 

$$\parallel B_2 
ightarrow S_2$$

$$\cdots$$

$$\parallel B_n 
ightarrow S_n$$
if

od

or simply **do**  $BB \rightarrow IF$  **od**.

This suggests that we could have got by with just the simple while-loop.

### A Theorem for Simple DO

Suppose there exist a predicate P and an integer-valued expression t such that

- 1.  $P \wedge B \Rightarrow wp(S, P)$ ,
- 2.  $P \Rightarrow (t \ge 0)$ , and
- 3.  $P \wedge B \wedge (t = t_0) \Rightarrow wp(S, t < t_0)$ , where  $t_0$  is a rigid variable.

Then  $P \Rightarrow wp(\mathbf{do} B \rightarrow S \mathbf{od}, P \land \neg B)$ .

This is to be contrasted by

$$\{P \wedge B\} S \{P\} \qquad \{P \wedge B \wedge t = Z\} S \{t < Z\} \qquad P \Rightarrow (t \ge 0)$$

 $\{P\}$  while B do S od  $\{P \land \neg B\}$
