Frama-C: Introduction

- Frama-C is an open-source extensible and collaborative platform dedicated to source-code analysis of C programs.
- With suitable plug-ins, it is a tool for formal verification (among several source-code analysis features) of C code with specification written in ACSL (ANSI/ISO C Specification Language).
- Two most relevant plug-ins for (Hoare Logic-based) formal verification are:
  - WP
  - Jessie

  Both in turn rely on external automatic or interactive provers such as Alt-Ergo and Coq to complete the verification tasks.
- Given an ACSL-annotated program, both WP and Jessie can generate verification conditions using weakest-precondition calculus and send them to designated provers.

Software Architecture

- The Frama-C kernel is based on a modified version of CIL, which is a front-end for C that parses ISO C99 programs into a normalized representation.
- Frama-C extends CIL to support ACSL.
- This modified CIL front-end produces the C + ACSL abstract syntax tree (AST), an abstract view of the program shared among all analyzers.
- Analyzers are developed as separate plug-ins on top of the kernel.
- Plug-ins are dynamically linked against the kernel to offer new analyses, or to modify existing ones.
- Any plug-in can register new services in a plug-in database stored in the kernel, thereby making these services available to all plug-ins.

ACSL: Introduction

- ACSL (ANSI/ISO C Specification Language) is a behavioral interface specification language implemented in the Frama-C framework.
- It allows for formally specifying the behavioral properties of a C program, in order to be able to formally verify the implementation with respect to these properties.
- ACSL was inspired by and resembles JML.

A First Example

```
1 /*@ ensures \result >= x && \result >= y;
2     ensures \result == x || \result == y;
3 */
4 int max (int x, int y) { return (x > y) ? x : y; }
```

- So, ACSL annotations are written in special C comments, the difference with plain comments being that annotations begin with `/*@`.
- It is also possible to write one-line annotations introduced by `//@`.
- The "function contract" is written immediately above the function declaration.
- In this example, the contract contains only post-conditions (`ensures` clauses), as max does not have any particular requirement.
- The keyword `\result` denotes the returned value of the function.

Regarding Formal Specifications

- Complete specification
  Any function that satisfies the specification should be deemed a satisfactory implementation.
- Partial specification
  Partial specifications express some of the properties that are expected to hold for any implementation.
- Generally speaking, partial formal specifications are the most likely to be encountered in practice for real-life examples.

An Example of Partial Specification

```
1 /*@ requires \valid(p) && \valid(q);
2     ensures *p <= *q;
3 */
4 void max_ptr(int *p, int *q)
5 {
6     *p = *q = 0;
7 }
```

- The `requires` clause specifies the pre-condition.
- The predicate `\valid(p)` indicates that the address p is included in an allocated block which is large enough to store an int starting at p.
- The partial specification may be met by an unwanted implementation.

Function Contract

```
1  /*@ requires n > 0;
2      requires \valid(p+ (0..n-1));
3      ensures \forall int i; 0 <= i <= n - 1 ==> \result >= p[i];
4      ensures \exists int e; 0 <= e <= n - 1 && \result == p[e];
5  */
6  int max_seq(int * p, int n) {
7    int res = *p;
8    for (int i = 0; i < n; i++) {
9      if (res < *p) { res = *p; }
10     p++;
11   }
12   return res;
13 }
```

Problem: the specification does not prevent the implementation from altering the integer array.

Function Contract (cont.)

```
1  /*@ requires n > 0;
2      requires \valid(p+ (0..n-1));
3      ensures \forall int i; 0 <= i <= n - 1 ==> p[i] == \old(p[i]);
4      ensures \forall int i; 0 <= i <= n - 1 ==> \result >= p[i];
5      ensures \exists int e; 0 <= e <= n - 1 && \result == p[e];
6  */
7  int max_seq(int * p, int n) {
8    int res = *p;
9    for (int i = 0; i < n; i++) {
10     if (res < *p) { res = *p; }
11     p++;
12   }
13   return res;
14 }
```

- The red line ensures that the content of the integer array is not modified.
- The built-in logic function `\old` gets the old (i.e., before the call) value of a given element.

Assigns Clauses

```
1  /*@ requires \valid(p) && \valid(q);
2      assigns *p, *q;
3  */
4  void swap (int *p, int *q) {
5    int tmp = *p;
6    *p = *q;
7    *q = tmp;
8    return;
9  }
```

- When no **assigns** clauses are specified, the function is allowed to modify any visible variable.
- If there are **assigns** clauses specified, the function can only modify the content of the locations that are explicitly mentioned in the clauses.

Assigns Clauses (cont.)

```
1  /*@ requires n > 0;
2      requires \valid(p+ (0..n-1));
3      assigns \nothing;
4      ensures \forall int i; 0 <= i <= n - 1 ==> \result >= p[i];
5      ensures \exists int e; 0 <= e <= n - 1 && \result == p[e];
6  */
7  int max_seq(int * p, int n) {
8    int res = *p;
9    for (int i = 0; i < n; i++) {
10     if (res < *p) { res = *p; }
11     p++;
12   }
13   return res;
14 }
```

The red line ensures that the integer array `p` and the integer `n` are not modified.

Loop Invariants

```
1  int max_seq (int* p, int n) {
2    int res = *p;
3    /*@ loop invariant
4        \forall integer j; 0 <= j <= i ==> res >= *(p + j);
5    */
6    for (int i = 0; i < n; i++) {
7      if (res < *p) { res = *p; }
8      p++;
9    }
10   return res;
11 }
```

Termination

- Termination is guaranteed by attaching a measure function to each loop and each recursive function.
- Loops are annotated by "`//@ loop variant e;`"
  For each iteration, the value of `e` at the end of the iteration must be smaller than its value at the beginning. Its value at the beginning must be nonnegative.
- Functions are annotated by "`//@ decreases e;`"
  Each function must be annotated with the same `decreases` clause. Any recursive call must occur in a state where the measure is smaller than the measure in the pre-state.
- Functions can also be annotated by "`//@ terminates p;`"
  If `p` holds, the function is guaranteed to terminate.

Termination (cont.)

```
1  /*@ assigns \nothing
2      terminates c > 0;
3  */
4  void f (int c) {
5    while(!c)
6      ;
7    return;
8  }
```

The function `f` can be called with any argument `c`, but the function is not guaranteed to terminate if `c <= 0`.

Assertions

```
1  /*@ requires n >= 0 && n < 100;
2  */
3  int f (int n) {
4    int tmp = 100 - n;
5    //@ assert tmp > 0;
6    //@ assert tmp < 100;
7    return tmp;
8  }
```

- An annotation "`assert p;`" means that `p` must hold in the current state.
- Assertions are useful to provide hints for the generation of verification conditions.

Behaviors

```
1  typedef enum { Max, Min } kind;
2
3  /*@ requires k == Max || k == Min;
4      assigns \nothing;
5      ensures \result == x || \result == y;
6      ensures k == Max ==> \result >= x && \result >= y;
7      ensures k == Min ==> \result <= x && \result <= y;
8  */
9  int extremum (kind k, int x, int y) {
10   return ((k == Max ? x > y : x < y) ? x : y);
11 }
```

This specification may not be clear to say that `extremum` has two distinct modes of operation.

Behaviors (cont.)

Behaviors allow us to specify the different cases for postconditions.

```
1  /*@ requires k == Max || k == Min;
2      assigns \nothing;
3      ensures \result == x || \result == y;
4      behavior is_max:
5        assumes k == Max;
6        ensures \result >= x && \result >= y;
7      behavior is_min:
8        assumes k == Min;
9        ensures \result <= x && \result <= y;
10     complete behaviors is_max, is_min;
11     disjoint behaviors is_max, is_min;
12 */
13 int extremum (kind k, int x, int y);
```

Constructs for Specifying Properties

- Predicates and functions provided by ACSL: `\valid`, `\separated`, `\old`, `\at`, etc.
- Logical types provided by ACSL: `integer`, `real`, etc.
  Mathematical integers and reals are more general than `int`s and `float`s in C.
- User-defined predicates and functions

```
1 /*@
2   predicate unchanged{L0, L1}(int* i) =
3     \at(*i, L0) == \at(*i, L1);
4 */
```

```
1 /*@
2   logic integer ax_b(integer a, integer x, integer b) =
3     a * x + b;
4 */
```

- Lemmas: user-specified properties about predicates and functions

Lemmas

- Lemmas can be proved in isolation of the rest of the proof of a program by automatic or (more often) interactive provers.
- Once the proof is done, the information that it states can be safely used to simplify the reasoning in other, more complex proofs, without having to prove it again.

```
1  /*@
2    lemma lt_plus_lt:
3      \forall integer i, j ; i < j ==> i+1 < j+1;
4  */
```

Inductive Definitions

Inductive predicates give a way to state properties whose verification requires reasoning by induction.

```
1  /*@
2    inductive zeroed{L}(int* a, integer b, integer e){
3    case zeroed_empty{L}:
4      \forall int* a, integer b, e; b >= e ==> zeroed{L}(a,b,e);
5    case zeroed_range{L}:
6      \forall int* a, integer b, e; b < e ==>
7        zeroed{L}(a,b,e-1) && a[e-1] == 0 ==> zeroed{L}(a,b,e);
8  }
9  */
```

Inductive Definitions (cont.)

```
1  /*@
2    requires \valid(array + (0 .. length-1));
3    assigns array[0 .. length-1];
4    ensures zeroed(array,0,length);
5  */
6  void reset(int* array, size_t length){
7    /*@
8      loop invariant 0 <= i <= length;
9      loop invariant zeroed(array,0,i);
10     loop assigns i, array[0 .. length-1];
11     loop variant length-i;
12   */
13   for(size_t i = 0; i < length; ++i)
14     array[i] = 0;
15 }
```

Axiomatic Definitions

Instead of defining directly a function or predicate, an axiomatic definition declares it and then defines axioms that specify its behavior.

```
1  /*@
2    axiomatic A_all_zeros{
3      predicate zeroed{L}(int* a, integer b, integer e)
4        reads a[b .. e-1];
5
6      axiom zeroed_empty{L}:
7        \forall int* a, integer b, e; b >= e ==> zeroed{L}(a,b,e);
8
9      axiom zeroed_range{L}:
10       \forall int* a, integer b, e; b < e ==>
11         zeroed{L}(a,b,e-1) && a[e-1] == 0 ==> zeroed{L}(a,b,e);
12   }
13 */
```

Ghost Variables

Ghost variables and statements are like C variables and statements, but visible only in the specification.

```
1  int max_seq (int* p, int n) {
2    int res = *p;
3    /*@ ghost int e = 0;
4        loop invariant \forall int j;
5                          0 <= j <= i ==> res >= p[j];
6        loop invariant \forall \valid(p+e) && p[e] == res;
7    */
8    for (int i = 0; i < n; i++) {
9      if (res < *p) {
10       res = *p;
11       //@ ghost e = i;
12     }
13     p++;
14   }
15   return res;
16 }
```
